At first, original three address codes will be got from compiler in this scheme, and sensitive data and state information of mobile agents will be encrypted using AMH, then three address codes operating code will be encrypted using composite function technology after first encryption. Double encryption problems of operands and operating code will encounter during the first and second encryption, that will arouse the incorrect encryption of mobile agent. So AMHCFES will find all operands and operating code statements which have been double encrypted, and take away such statements. Double encryption problems will be solved to every encryption process. Encrypted three address codes will be created in AMHCFES, this codes execute the same task as original three address codes and get the same effect. But encrypted three address codes are hard for malicious host to read and modify mobile agents' code, data and state information.

### *3.1 AMHCFES Idea*

The process description of encryption and decryption is given in Fig.2 . When encrypting, AMH is used to encrypt data, a simple function, that is $g(x)=x^3+1$ is used to encrypt operating codes. Then the encrypted mobile agent is sent to other hosts in network directly and results are returned to the original host. When decrypting, the reverse function $g^{-1}(x)=\sqrt[3]{x-1}$ is used first, then AMH scheme is used to get the real return results.

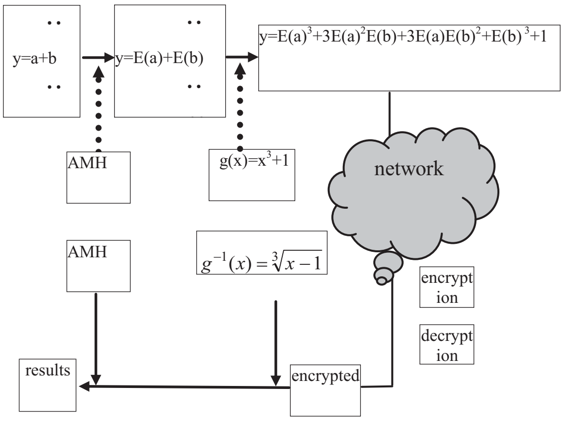

Fig.2 Encryption and Decryption Procedure

### *3.2 AMHCFES Algorithm*

A great number n is used in the algorithm, which makes $n=p\times q$ , *p* and *q* are prime numbers in this expression. Set $Z_p=\{x|x\le p\}$ as original plaintext information set, and set $Z_n=\{x|\ x<n\}$ as ciphertext information set, $Q_p=\{a|\ a\not\in Z_p\}$ is the clue set of encryption.

Addition and Multiplication operating type are defined on $Z_p$.

The encryption and decryption algorithms are as follows:

(1) Encryption algorithm: To given $x\in Z_p$ choosing a random a in $Q_p$, and making x = a mod p. Encrypted result is calculated as y = Ep(x) = a mod n.(This is also can be done by choosing a random r and creating a expression a = x +rp.)

(2) Decryption algorithm: To given $y=E_p(x)\in Z_n$ , using cryptographic key p to recover original value x = Dp(y) = y mod p.

A plain information x can be encrypted into more kinds of ciphertext in this cryptosystem. So, although $E_1(x) \neq E_2(x)$ but D(E1(x)) = D(E2(x)).

### *3.2.1 The Correctness Proof of Algorithm*

Here, theorem 3.1 is given to show the correctness of algorithm, and the proof process will be given.

Theorem 3.1: To all $x \in Z_p$ , existing Dp (Ep(x)) = x.

Proof: let $y = E_p(x)$ and random a is used to encrypt information, exists

a mod n = y (3.1)

Then divide n by p, equality (3.1) meaning

y mod p = (a mod n) mod p = x (3.2)

Done.

The proof of Algorithm AMHCFES's addition and multiplication properties which based on mod n is as follows:

Theorem 3.2: To all s and t in Zp , existing D(E(s)t) = D(E(st)).

Proof: Let's calculate E(s) t and E(s t) first.

(1) E(s) t : In order to encrypt s, let's choose a value $a_1$, make s = $a_1$ mod p, that is obtain the expression $a_1 = k_1 p + s$ , as $y_1 = a_1 \bmod n$ ,so $a_1 = k_2 n + y_1$ ,and then get the expression $k_1 p + s = k_2 n + y_{11}$ .Thus, $y_1$ is obtained.

$$y_1 = k_1 p - k_2 n + s = (k_1 - k_2 q)p + s \qquad (3.3)$$

As $E(s) = y_1, E(s)t = y_1 t$ , get

$$y_1 t = (tk_1 - tk_2 q)p + ts$$

Obtaining the equality through decryption:

$$D(E(s)t) = D(y_1 t) = y_1 t \bmod p = st \qquad (3.4)$$

(2) E(st): In order to encrypt st, let's choose a value $a_2$, make st = $a_2$ mod p, that is $a_2 = k_3 p + st$ , so st is encrypted as $y_2 = a_2 \bmod n$ , that is $a_2 = k_4 n + y_2$ , Obtaining $y_2$ through calculation: $y_2 = (k_3 - k_4 q)p + st$

Obtaining equality through decryption:

$$D(E(st)) = D(y_2) = y_2 \bmod p = st \qquad (3.5)$$

(3) D(E(s)t) = D(E(t)) : Obtaining the results from equality (4) and (5) :

$$y_1 t \bmod p = y_2 \bmod p = st$$

Which means, existing D(E(s)t) = D(E(t)) based on mod p. Done.

### *3.2.2 Examples of Algorithm AMHCFES*

Any input random t can be encrypted automatically using this algorithm[19]. The auto encryption property of algorithm AMHCFES is shown by following example.

E.g. supposing p=101, q=71, then n = pq =7171. For the same reason, supposing host of mobile agent provides E(1) =203. Malicious host hope the input vnumber 8 encrypted, then letthe encrypted number 8 multiply E(1), and obtain ciphertext,that is E(8) =1624. In order to test the equality, choosing A=15966, then 15966 mod 7171 = 1624.

Attention : As A∈Qn..={ A|(A ∉ Zn ) ∩ ( A ≥ n )} , then 1624 mod 101 = 8.

### *3.3 Verification of AMHCFES Security*

This scheme is decrypted by calculating x = y mod p, and the security of this algorithm may be tested by arguments on safety[20-21].

Ciphertext Attack: as y∈ Zq , if cryptanalysts want to find number A∈ Qn , they don't need to get p, but they need p to calculate a mod p = x. So, it is difficult for cryptanalysts to find p in module n, the same as factoring to n, if they know cipher only. So it is hard to find initial values only knowing cipher.

Plaintext Attack: if cryptanalysts know a pair of plaintext-cipher(x, y), then they create a data set of t, that is Ai∈ Qn, i = 1,⋯,t, so Ai = y mod n. To every i, there is Ai = x mod p, so p|(Ai – x), p = gcdti=1(Ai – x). But it is hard to let such thing happens.

Integrity Attack: Since module p is needed by all to execute decryption, any open data such as x < p can be used to decrypt data. So malicious host may choose a value to replace any encrypted data[22-24]. But such choice is blind as module p isn't known. It is hard to find initial values.

## IV. CONCLUSION

This scheme provides a new method to encrypt information without any secret key. MA encrypted by AMHCFES can execute tasks on other hosts of network without decryption. It is effective to defend attacks of malicious hosts.

### *4.1 Shortcoming*

There are some restrictions and assumptions in this scheme, which restrict application scope of the scheme.

Assumption 1: This scheme is used for Integer since AMH is based on loop theory.

Assumption 2: Control structure of MA codes can not be encrypted by composite function, because such operators are included in control structure, e.g. logical expression with other type operators in if statements, other operators here are: logical operator, Boolean operator, assignment operator, etc.

### *4.2 Improvement*

Further study is needed to improve scheme, the work will be done in future is as follows:

Data set handled in this scheme is integer because of loop theory assumption. In order to further expand application scope of MA protection, researching how to expand data set to other data types is the study focus afterwards.

In MA encryption algorithm, type of function call are limited to some basic input output statements, so valid calling method of user defined function and system function will be studied.

***Abstract*—In this paper, we study adaptive control design problem of piecewise-linear systems with matching parametric uncertainties. The basic idea is to construct a piecewise control law and a piecewise parameter adaptation law in such a way that a piecewise quadric Lyapunov function can be used to establish the global stability. All of the synthesis conditions are formulated as Linear Matrix Inequities and can therefore be efficiently solved. Moreover, the possibility of sliding motion at the boundary of polytopic regions is considered, and the results are demonstrated by application to control a linear motor.**

## I. Introduction

Piecewise linear(PWL) systems are switched linear systems with state space-partition-based switching. PWL systems are very important in representing many practical systems including power electronics [1], [2], robots [3], [4] and biology regulatory networks [5]. In additional, PWL systems can approximate nonlinear systems to any degree of accuracy and therefore provide a useful framework for the analysis and synthesis of a large class of nonlinear systems.

Remarkable progress on the PWL systems have been achieved thanks to the dedication of many researchers over the last decades. Important achievements include stability and stabilization [6]–[11], state and output tracking control [12]–[14] and robust control of PWL systems [15]–[20] among others.

Although the proposed robust control methods [15]–[20] can be applied to deal with the uncertain PWL systems, model uncertainties coming from parametric uncertainties can not be reduced. In order to achieve the required performance, the feedback gains must be increased, resulting in high-gain feedback. On the other hand, there are always the constrain scope of control input in the practical engineering systems. To avoid the high-gain feedback, an Lyapunov-based adaptive control approach was proposed in [21]. However, the synthesis conditions were formulated as Bilinear Matrix Inequities(BMIs), the computation problem of BMIs is still a common challenge.

In this paper, we study the adaptive control design problem of PWL systems with matching parametric uncertainties. The basic idea is to construct a piecewise control law and a piecewise parameter adaptation law in such a way that a piecewise quadric Lyapunov function[PQLF] can be used to establish the global stability. Comparing with [21], all of the synthesis conditions are formulated as Linear Matrix Inequities(LMIs) instead of BMIs, thus are much more simple to solve with existing software such as MATLAB. Moreover, we consider the possibility of sliding motion at the boundary of polytopic regions, which guarantees the rigidity of the proposed approach.

## II. Problem Formulation and Preliminary

Consider the following uncertain PWL systems,

$$\dot{x} = \begin{cases} A_1 x + B_1 u + \varphi_1(x)\theta & \text{if } x \in R_1, \\ A_2 x + B_2 u + \varphi_2(x)\theta & \text{if } x \in R_2, \\ \cdots & \\ A_m x + B_m u + \varphi_m(x)\theta & \text{if } x \in \mathcal{R}_m, \end{cases} \tag{1}$$

where $\mathbb{R}^n = \cup_{i \in \{1,2,\cdots,m\}} R_i$ denotes a partition of the state space into a number of closed polytopic regions; $x \in \mathbb{R}^{n_x}$, $u \in \mathbb{R}^{n_u}$ and $\theta \in \mathbb{R}^{n_\theta}$, denotes the state, input and unknown parameter vector, respectively. Moreover, $A_i, B_i$ are all constant matrices with appropriate dimensions; $\varphi_i(x) : \mathbb{R}^{n_x} \rightarrow \mathbb{R}^{n_x \times n_\theta}$ is a continuous linear or nonlinear function with $\varphi_i(0) = 0$.

As shown in [6], we can construct matrices $E_i$, $F_i$ for each region $R_i$ such that

$$\begin{cases} E_i x \geq 0, & x \in R_i \\ F_i x = F_j x, & x \in R_i \cap R_j \end{cases} \tag{2}$$

*Assumption 1:* The proposed PWL systems satisfy the matching condition, i.e., there exist function $\psi_i(x)$ for each region, such that

$$B_i \psi_i(x) = \varphi_i(x), \quad x \in R_i. \tag{3}$$

Let $\hat{\theta}$ be the estimation of $\theta$, our objectives are to design a piecewise control law $u(t) = u_i(x, \hat{\theta}), x \in R_i$ and a piecewise parameter adaptation law $\dot{\hat{\theta}} = \upsilon_i(x, \hat{\theta}), x \in \mathcal{R}_i$, such that the closed-loop PWL system is asymptotically stable, i.e, all the possible state trajectories will converge to origin.

## III. Main Results

In this section, we provide the main contribution of the paper. An LMI-based adaptive control approach will be devel-

978-1-4673-1560-9/12/$31.00 ©2012 IEEE

oped for the PWL system (1) based on the PQLF theory [6] and the following two lemmas.

*Lemma 1:* [22] For all positive definite matrices $P$, the following inequality holds:

$$G^TP^{-1}G \geq G^T + G - P. \tag{4}$$

*Lemma 2:* [23] Let $\Phi$ be any given positive definite matrix. The following statements are equivalent:

$$\begin{array}{l} (1).\ \Psi + \Xi + \Xi^T < 0; \\ (2).\ \text{There exists a matrix } W \text{ such that} \\ \begin{bmatrix} \Psi + \Phi - (W + W^T) & \Xi^T + W^T \\ * & -\Phi \end{bmatrix} < 0. \end{array} \tag{5}$$

Now, we give the main result of this paper.

*Theorem 1:* If there exist symmetric matrices $T$, $U_i$, $W_i$ and general matrix $V_i$, $R_i$, such that $U_i$, $W_i$ have nonnegative entries and the following LMIs are satisfied with $P_i = F_i^TTF_i$,

$$P_i - E_i^TW_iE_i > 0, \tag{6}$$

$$\begin{bmatrix} -(V_i + V_i^T) & V_i^TA_i^T + R_i^TB_i^T + P_i & V_i^T \\ * & -P_i & 0 \\ * & * & E_i^TU_iE_i - P_i \end{bmatrix} < 0. \tag{7}$$

Then, using the piecewise control law

$$\begin{cases} u = -\psi_i(x)\hat{\theta} + K_ix \\ K_i = -R_iV_i^{-1} \end{cases} \quad x \in \mathcal{R}_i \tag{8}$$

and the piecewise parameter adaptation law

$$\dot{\hat{\theta}} = \varphi_i(x)^TP_ix, \quad x \in \mathcal{R}_i, \tag{9}$$

the resulting closed-loop PWL system is asymptotically stable.

**Proof:** We choose a piecewise quadratic Lyapunov function

$$V(x, \hat{\theta}) = \sum_i \beta_i[x^TP_ix + \tilde{\theta}^T\tilde{\theta}],\ \beta_i = \begin{cases} 1 & x \in R_i \\ 0 & \text{others} \end{cases} \tag{10}$$

where $\tilde{\theta} = \hat{\theta} - \theta$ denotes the estimation error of unknown parameter $\theta$.

Then, the sufficient conditions for the asymptotical stability are

$$\begin{cases} V(x, \hat{\theta}) \geq 0 \\ \dot{V}(x, \hat{\theta}) < 0 \end{cases} \tag{11}$$

That is because if considering the augmented system (1),(8),(9), and let

$$E = \{(x, \hat{\theta}) \in (X, \mathbb{R}^{n_\theta}) | \dot{V}(x, \hat{\theta}) = 0\} \tag{12}$$

then

$$E = \{(0, \theta_1) | \theta_1 \in \mathbb{R}^{n_\theta}\} \tag{13}$$

and $E$ is a invariant set. Therefore,using LaSalle's theorem[25], the solution of the augmented system $(x(t), \hat{\theta}(t))$ converges to the set E, i.e.,

$$\lim_{t \to \infty} x(t) = 0 \tag{14}$$

Therefore, we just need to show the conditions (11) hold. With the help of (10), we learn that the conditions (11) can be implied by

$$\begin{cases} x^TP_ix > 0 \\ 2\dot{x}^TP_ix + 2\tilde{\theta}^T\dot{\hat{\theta}} < 0 \end{cases} \quad x \in R_i \setminus 0\ . \tag{15}$$

Replacing the piecewise control law and adaptation law by (8–9), the sufficient conditions become

$$\begin{cases} x^TP_ix > 0 \\ 2(\bar{A}_ix + \varphi_i(x)\theta - B_i\psi_i(x)\hat{\theta})^TP_ix + 2\tilde{\theta}^T\varphi_i(x)^TP_ix < 0 \end{cases} \tag{16}$$

where $\bar{A}_i = A_i + B_iK_i$.

By eliminating the terms containing $\tilde{\theta}$, the sufficient conditions can be reformulated as the following inequalities

$$\begin{cases} x^TP_ix > 0 \\ x^T(\bar{A}_i^TP_i + P_i\bar{A}_i)x < 0 \end{cases} \quad x \in R_i\ . \tag{17}$$

These conditions can be relaxed using S-procedure and the polyopic region description (2), yielding the sufficient conditions as

$$\begin{cases} P_i - E_i^TW_iE_i > 0 \\ \bar{A}_i^TP_i + P_i\bar{A}_i + E_i^TU_iE_i < 0 \end{cases} \quad x \in R_i\ . \tag{18}$$

It is noted that the first inequality of the above conditions is same with (6), so our rest work is to show the proof of second inequality using condition (7).

Let $Q_i = P_i^{-1}$, $S_i = E_i^TU_iE_i$, then the second inequality can be written as

$$Q_i\bar{A}_i^T + \bar{A}_iQ_i + Q_iS_iQ_i < 0 \quad x \in R_i. \tag{19}$$

The use of Lemma 2 with $\Psi = Q_iS_iQ_i$ and $\Xi = Q_i\bar{A}_i^T$ yields,

$$\begin{bmatrix} Q_iS_iQ_i + \Phi_i - (W_i + W_i^T) & \bar{A}_iQ_i + W_i^T \\ * & -\Phi_i \end{bmatrix} < 0. \tag{20}$$

By the congruence transformation $\begin{bmatrix} V_i & 0 \\ * & P_i \end{bmatrix}$ with $V_i = W_i^{-1}$, the inequality (20) becomes

$$\begin{bmatrix} V_i^T(P_i^{-1}S_iP_i^{-1} + \Phi_i)V_i - (V_i + V_i^T) & V_i^T\bar{A}_i + P_i \\ * & -P_i\Phi_iP_i \end{bmatrix} < 0. \tag{21}$$

A Schur complement argument on the term $V_i^T(P_i^{-1}S_iP_i^{-1} + \Phi_i)V_i$ shows that, the sufficient condition is equivalent to the following inequality

$$\begin{bmatrix} -(V_i + V_i^T) & V_i^T\bar{A}_i + P_i & V_i^T \\ * & -P_i\Phi_iP_i & 0 \\ * & * & -(P_i^{-1}S_iP_i^{-1} + \Phi_i)^{-1} \end{bmatrix} < 0. \tag{22}$$

The use of Lemma 1 with $\Phi_i = P_i^{-1}$ yields,

$$(P_i^{-1}S_iP_i^{-1} + \Phi_i)^{-1} = P_i(S_i + P_i)^{-1}P_i \geq P_i - S_i. \tag{23}$$

This inequality show that the following condition implies the inequality (22),

$$\begin{bmatrix} -(V_i + V_i^T) & V_i^T\bar{A}_i + P_i & V_i^T \\ * & -P_i & 0 \\ * & * & E_i^TU_iE_i - P_i \end{bmatrix} < 0. \tag{24}$$

Replacing $\bar{A}_i$ by $\bar{A}_i^T$, we can obtain the dual of (25) as

$$\begin{bmatrix} -(V_i+V_i^T) & V_i^T\bar{A}_i^T+P_i & V_i^T \\ * & -P_i & 0 \\ * & * & E_i^TU_iE_i-P_i \end{bmatrix} < 0. \quad (25)$$

substituting $\bar{A}_i = \bar{A}_i + B_iK_i$, $R_i = K_iV_i$ into (25), we obtain the inequality 7. In summary, (6–7) are the sufficient conditions for the the asymptotical stability of the resulting closed-loop PWL SYSTEM, which completes the proof.

*Remark 1:* Although the proposed piecewise adaption law can only ensure the boundedness of $\hat{\theta}$ rather than asymptotical convergence to the true parameter value $\theta$, the state trajectory will still converge to the origin as the disturbance converges to zero.

## IV. Simulation Results

In this section, we consider an epoxy core linear motor drive system with negligible electrical dynamics described in the following [24].

$$\dot{x_1} = x_2 \quad (26)$$
$$M\dot{x_2} = u - \theta x_2 + [f_c - f_c e^{-|\dot{x_1}|}]sgn(\dot{x_1}) \quad (27)$$

where $x_1$, $x_2$ are the position and speed of the inertia load, respectively. The control input is $u$, which ensures the system stable. All the parameter values and their physical meanings are illustrated in Table 1, where $\theta \in [0.2, 0.28]$ is the uncertain parameter.

TABLE I: Simulation parameters

| | |
|---|---|
| $M$=0.55 | Motor mass (Kg) |
| $f_c$=1 | the Coulomb friction force |
| $\theta \in [0.2, 0.28]$ | an equivalent viscous friction coefficient |

The objective is to design a state feedback controller with the control gain constrain $\|K\|_\infty \leq 2$ that forces the motor to stop at a certain point.

Given the possible initial velocity $x_2 \in [-2, 2]$. The nonlinear function (27) – (28) can be approximated by PWA functions yielding a PWL system with four regions as below.

$$R_1 = \{x|x \in \mathbb{R}^2|x_2 \in [-2, -1]\},$$
$$R_2 = \{x|x \in \mathbb{R}^2|x_2 \in [-1, 0]\},$$
$$R_3 = \{x|x \in \mathbb{R}^2|x_2 \in [0, 1]\},$$
$$R_4 = \{x|x \in \mathbb{R}^2|x_2 \in [1, 2]\}.$$

Moreover, the system matrix $A_i$ is obtained by its PWA approximation, and

$$A_1 = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0.6645 & -0.2690 \\ 0 & 0 & 0 \end{bmatrix} \quad (28)$$
$$A_2 = A_3 = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 1.8182 & 0 \\ 0 & 0 & 0 \end{bmatrix}$$
$$A_4 = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0.6645 & 0.2690 \\ 0 & 0 & 0 \end{bmatrix}$$
$$B_i = \begin{bmatrix} 0 \\ 1.8182 \\ 0 \end{bmatrix}, \quad i \in \{1, 2, 3, 4\}$$

such as

$$\dot{\overline{x}} = A_i\overline{x} + B_iu + \varphi_i\theta \quad (29)$$
$$where\ \overline{x} = \begin{bmatrix} x_1 \\ x_2 \\ 1 \end{bmatrix}\ and\ \varphi_i(x) = \begin{bmatrix} 0 \\ -x_2 \\ 0 \end{bmatrix}. \quad (30)$$

Thus, the Assumption 1 is satisfied, where $\psi_i(x)$=$-0.55x_2$. Therefore, the following piecewise control law and parameter adaptation law are employed,

$$\begin{cases} u = 2\overline{x}_2\hat{\theta} + K_i\overline{x} \\ \dot{\hat{\theta}} = \varphi_i(\overline{x})^TP_i\overline{x} \end{cases} \quad x \in R_i\ , \quad (31)$$

where $K_i$ and $P_i$ can be obtained by solving the LMIs proposed in Theorem 1. The solutions are obtained by MATLAB as below.

$$K_1 = \begin{bmatrix} -0.7003 & -1.1917 & 0.2382 \end{bmatrix} \quad (32)$$
$$K_2 = \begin{bmatrix} -0.6106 & -1.9195 & 0.0118 \end{bmatrix}$$

$$K_3 = \begin{bmatrix} -0.5024 & -1.8053 & -0.0158 \end{bmatrix} \quad (33)$$
$$K_4 = \begin{bmatrix} -0.4098 & -0.8887 & -0.1969 \end{bmatrix}$$

Simulations have been carried out with the initial condition $[x_1, x_2]$=$[-2, -1.5]$ and $\hat{\theta}(0)$=0.24. Fig.1 shows that, the state trajectory of closed-loop PWL system converges to the origin, which illustrates the efficacy of the proposed LMI-based adaptive control method.

For comparison, we try to design the state feedback controller using the BMI-based adaptive control method [21] for the same PWL system, no feasible solution can be found using YALMIP, which illustrates the advantage of the proposed LMI-based adaptive control approach.

## V. A Remark on Sliding Motion

Actually, by extending the idea of [6], if there exists a quadratic Lyapunov function $V_l(x, \tilde{\theta}) \geq 0$ for each boundary

$l = R_i \cap R_j$, such that for all $x \in l$,

$$V_l(x, \tilde{\theta}) \geq 0 \tag{34}$$

$$\frac{\partial V_l}{\partial x}\bar{co}\{A_{\tau k}x + B_\tau u + \varphi_\tau(x)\theta\} + \frac{\partial V_l}{\partial \tilde{\theta}}\dot{\tilde{\theta}} < 0, \tau = i, j \tag{35}$$

the asymptotical stability can be guaranteed, although the sliding motion may happen. Note that for all $x \in l$, $E_l x = 0$, then using similar procedure in the proof of Theorem 1, the constraints (34-35) can also be expressed as LMIs.

## VI. Conclusion

In this paper, a LMI-based adaptive control method is developed for uncertain PWL systems. By constructing proper piecewise model compensator and online parameter adaptation law, the adaptive control design problem can be converted to the control design problem for a nominal PWL system without parameter uncertainties. Furthermore, the stabilization problem for the obtained nominal PWL system are formulated as optimization problems subject to a set of LMIs, which are numerical solvable by the existing software. However, the proposed method still has a limitation that the parametric uncertainty of the PWL systems must satisfy matching condition, which will restrict the application of the proposed synthesis method. Therefore, our future work will focus on how to get rid of this assumption to achieve wider applications.

***Abstract*—Based on total variation minimization (TV) algorithm and the theory of polynomial acceleration, we prompted a modified algorithm, which is called P-TV in this paper. This new algorithm has a better noise immunity and fewer iteration numbers than the traditional TV algorithm. P-TV algorithm can be divided into four steps. Compared to the traditional TV algorithm, the P-TV algorithm applies the theory of polynomials to ART iteration step to enforce data consistency with the projection data and applies the positivity constraint after the GRAD-step too, which accelerate convergence of image reconstruction. Simulation results prove that when the iteration number is the same, the quality of reconstructed image from P-TV algorithm is better than traditional TV algorithm. When the quality of image reconstructed by both algorithms is nearly the same, the iteration number of P-TV algorithm is much less than the number of traditional TV algorithm. At last we applied the two algorithms to CT image reconstruction from the noisy data. All results show that the P-TV algorithm is effective.**

***Index Terms*—CT; Few-views; Image reconstruction; TV algorithm; Polynomial acceleration algorithm**

## I. Introduction

Computed Tomography (CT) image reconstruction is widely used in medicine, industrial inspection and so on. It is an imaging technique to get the cross-sectional information of the image according to projection measurement data which are in different angles. In various forms of computerized tomographic image reconstruction, one of the main issues centers on how to estimate an accurate image from few views data. In two dimensional (2D) CT, the most common problems are the non-sufficient data reconstruction problems[1][2]. Here, we focus on the few-views problem, which obtains the projection data only in some specific angles. Two widely used iterative algorithms for tomographic reconstruction are the algebraic reconstruction technique (ART) [3]and the expectation-maximization (EM) algorithm[4]. For the case where the data are not sufficient to determine a unique solution to the imaging model, the ART algorithm will find the imagethat is consistent with the data and minimizes the sum-of-squares of the image pixel values. But this algorithm will lead to conspicuous artifacts in reconstructed images. Although there are many improvements based on ART, such as SIRT and MART, the effect on elimination of artifacts is not so obvious. In the last few years, total variation minimization (TV) methods, which originates in the field of compressing sensing (CS)[5][6], for CT reconstruction from sparse and noisy data were developed by Sidky et al [7]. This method is effective on artifacts elimination; we can get a high quality reconstruction image with it. Li Yi of North University of China and Liu Baodong of Chongqing University of China both make some modifications about TV algorithm [8][9]. But traditional TV algorithm is time consuming. In this paper, we develop an iterative image reconstruction algorithm, which is combined TV algorithm with theory of polynomial acceleration[10]. We call it P-TV algorithm which accelerates convergence of image reconstruction. Each iteration of P-TV algorithm can be divided into four steps: the POCS-step (Projection onto Convex Sets), which applies the theory of polynomials to ART iteration to enforce data consistency with the projection data; the positivity constraint step, which constrains the values of all reconstructed points within [0, 1]; the GRAD-step, which reduces the TV of the image estimate; the positivity constraint step again, this step is added to the conditional TV algorithm additionally, which can accelerate convergence of image reconstruction.

This paper is organized as follows. In Section2, we describe the CT reconstruction problem and the TV algorithm. In Section 3, we introduce the theory of polynomial acceleration and promote the modified TV algorithm. In Section4, we give the numerical simulation results. In Section5, we conclude this paper.

## II. TV ALGORITHM

### *A. Mathematic Model of CT reconstruction*

The image is described by a vector $\vec{f}$ of length $N_{image}$ with elements$f_j, j = 1, 2N_{image}$, $N_{image} = n \times n$ where the

978-1-4673-1560-9/12/$31.00 ©2012 IEEE

integer n is the width and height of the 2D image array. The projection-data is described by a vector $\vec{p}$ of length $N_{data}$with elements $p_i$

$$p_i = \sum_{j=1}^{N_{image}} w_{ij} f_j, i = 1, 2, \ldots, N_{data} \tag{1}$$

$N_{data}$ is the total number of projection-data. $w_{ij}$ is the element of the system matrixrepresent the impact of pixel $f_j$ to projection-data $p_i$ and the value of $w_{ij}$ is equal to the length of ith projection through the jth pixel[11]. The system matrix W is composed of $N_{data}$ row vectors. The general expression for the algorithm discussed here involves inversion of a discrete-to-discrete linear transform

$$\vec{p} = W\vec{f} \tag{2}$$

### B. TV algorithm

CT reconstruction always is an ill-posed problem, especially when it is few-views condition. The typical method to solve this problem is the regularization. Recently, regularization based on minimizing TV of the image becomes a hot topic[7][12-15].In fact, minimizing TV of the image is a progress to minimize the $l_1$-norm of the gradient image. So, the most elements of gradient image will be zeros and the original image will tend to constant in most pixels [16]. Each iteration of TV algorithm consists of two phases: POCS and gradient descent. The POCS phase is further broken down into two steps that enforce data consistency and positivity. As a result, the steps comprising each loop are: DATA-step, which enforces data consistency with the projection data; the POS-step, which ensures a non-negative image; and the GRAD-step, which reduces the TV of the image estimate. We can refer to references[7] for concrete steps of TV algorithm. During the process of DATA-step, TV algorithm employs the traditional ART iteration formula to enforce data consistency. And in the process of GRAD-step, parameter  is a constant, which is used to control the convergence speed. So, in the beginning of iteration, $f^{(TV\_GRAD)}$ will fall off rapidly to certain value. But with the increase of iteration, $f^{(TV\_GRAD)}$ will fall off slowly. Therefore, we prompted a modified TV algorithm, called it P-TV based on TV algorithm and the theory of polynomial acceleration, which will introduce below. P-TV algorithm has a better performance in convergence speed than TV algorithm. This performance will be discussed in Section 4.

## III. THEORY OF POLYNOMIAL ACCELERATION

The traditional iteration method just used the information of image in last step, such as ART. The theory of polynomial acceleration will use all the information in each iteration[10]. The general formula is as follows:

$$F^k = u_1 F^{k-1} + u_2 F^{k-2} + \ldots + u_k F^0 + w_k r^{k-1} \tag{3}$$

$$k = 1, 2, \ldots, u_1 + u_2 + \ldots + u_k = 1, w_k \neq 0$$

$r^{k-1}$ is remainder term. We can obtain the following formula from (3)

$$F^k - F^0 = \sum_{j=0}^{k-1} \varepsilon_j (W^* W)^j r_0 = q^{k-1}(W^* W) r_0 \tag{4}$$

$$q^{k-1}(\gamma) = \varepsilon_0 + \varepsilon_1 \gamma + \ldots + \varepsilon_{k-1} \gamma^{k-1} \tag{5}$$

$q^{k-1}(\gamma)$ is a polynomial of K-1 order and

$$q^{k-1}(\gamma) = \sum_{j=0}^{k-1} (1-\gamma)^j = \frac{1-(1-\gamma)^k}{\gamma} \tag{6}$$

In order to use polynomial iteration effectively, promoting an algorithm just used the information of $F^{k-1}$ and$F^{k-2}$.

$$F^k = F^{k-1} + u_k (F^{k-1} - F^{k-2}) + w_k W^* (P - W F^{k-1}) \tag{7}$$

$$u_k = \frac{(k-1)(2k-3)(2k+2v+1)}{(k+2v-1)(2k+4v-1)(2k+2v-3)} \tag{8}$$

$$w_k = \frac{(k+v-1)(2k+2v-1)}{(k+2v-1)(2k+4v-1)} \tag{9}$$

We combined this theory with TV algorithm, the improved algorithm of TV are as follows:

*1) Initialization:*

$$f^{(0)} = 0, \alpha = 0.2, N_{grad} = 20, v = 0.8$$

*2) Data projection iteration, for $k = 1, 2, \ldots, N_{data}$:*

$$f^{(k)} = f^{(k-1)} + u_k (f^{(k-1)} - f^{(k-2)}) + w_k \frac{p_i - w_{ij} f^{(k-1)}}{\sum_{j=1}^{N_{image}} w_{ij}^2} w_{ij} \tag{10}$$

$$i = 1, 2 \ldots, N_{data} \; j = 1, 2 \ldots, N_{image}$$

$$u_k = \frac{(k-1)(2k-3)(2k+2v+1)}{(k+2v-1)(2k+4v-1)(2k+2v-3)} \tag{11}$$

$$w_k = \frac{(k+v-1)(2k+2v-1)}{(k+2v-1)(2k+4v-1)} \tag{12}$$

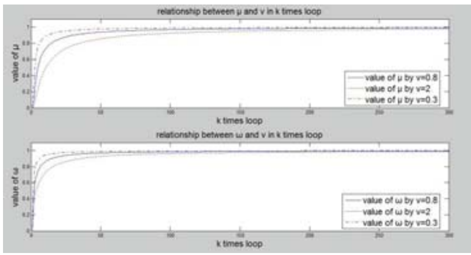

Fig. 1. tendency of $u_k$ and $w_k$ with the addition of iteration number

Fig.1. show the tendency of $u_k$ and $w_k$ with the addition of iteration number. v is a constant which controls the convergence rate of iteration. We can see from Figure, different value of v will lead to different convergence rate about $u_k$ and $w_k$ .Furthermore, different $u_k$ and $w_k$ will lead to different convergence rate in reconstruction iteration. Here, we set v=0.8 according to lots of experiments.

*3) Positivity constraint:*

$$f_{pose}^{(k)} = \begin{cases} 1, & f_j^{(TV\_GRAD)} > 1 \\ f_j^{(k)}, & 0 < f_j^{(TV\_GRAD)} < 1 \\ 0, & else \end{cases} \tag{13}$$

$$j = 1, 2 \ldots, N_{image}$$

*4) TV gradient descent initialization:*

$$d_A(n) = \|f^{(k-1)} - f_{pose}^{(k)}\| \tag{14}$$

$$f^{(TV\_GRAD)} = f_{pose}^{(k)} \tag{15}$$

*5) TV gradient descent for $m = 1, 2, \ldots N_{grad}$:*

$$v_j^{(m)} = \frac{\partial \|f^{(TV\_GRAD)}\|_{TV}}{\partial f_j^{(TV\_GRAD)}} \tag{16}$$

$$f^{(TV\_GRAD)} = f^{(TV\_GRAD)} - \alpha d_A \frac{v_j^{(m)}}{\|v_j^{(m)}\|} \tag{17}$$

*6) Positivity constraint:*

$$f_{pose}^{(TV\_GRAD)} = \begin{cases} 1, & f_j^{(TV\_GRAD)} > 1 \\ f_j^{(TV\_GRAD)}, & 0 < f_j^{(TV\_GRAD)} < 1 \\ 0, & else \end{cases} \tag{18}$$

*7) Stop condition:* The iteration will stop when there is no appreciable change in following formula, else return to 2).

$$|f_{pose}^{(k)} - f_{pose}^{(k-1)}| < \varepsilon \tag{19}$$

## IV. NUMERICAL SIMULATION RESULTS

The true image solution is taken to be the Shepp-Logan image shown in below discredited on a 128*128 pixel grid. This phantom is often used in evaluating tomographic reconstruction algorithms. We take parallel beam in experiment and scanning parameters are given in table 1.

TABLE I
SCANNING PARAMETERS

| Parameters | Values |
|---|---|
| Image size(pixel) | 128*128 |
| Projection group number | 18(every $10^o$) |
| Detector number | 185 |
| Angular range | $[0, \pi]$ |

For comparison, the images are reconstructed by use of TV algorithm and P-TV algorithm. Fig.2. Show the reconstructions results from noiseless data. It is shown clearly when the iteration number is same (both are 39), the reconstruct image quality of P-TV is better than TV.

For further comparison, we compare the image profiles [8] of line 50 and line 103 as fig.3. We can see image reconstructed by P-TV algorithm is closer to the original image than image reconstructed by TV algorithmespecially in some peak value. In order to show the P-TV algorithm's good performance on convergence speed, we show a group of pictures as below. Picture (b) is obtained by P-TV algorithm, picture (c) is reconstructed by traditional TV algorithm. We can see that the quality of picture (b) and picture (c) is nearly the same, but the iteration number of picture (c) is 305 while the iteration number of picture (b) is only 39. That is to say, P-TV algorithm's convergence rate is nearly ten times as much as TV algorithm.

Fig. 4. Reconstruct Image (a) original image; (b) reconstructed image by P-TV algorithm; (c) reconstructed image by TV algorithm

To verify the algorithm's stability for noise, we have also applied the two algorithms to noisy data generated by adding Gaussian noise to the projection data. The standard deviation of the Gaussian noise is $0.1\%$ of the maximum value of the projection data. The results are shown in Fig.5. It indicates that P-TV algorithm has better noise immunity than TV algorithm.

We also show the mean square error (MSE) of the reconstructed images used two algorithms and give them in Fig.6. We can see P-TV algorithm converge faster than TV algorithm and MSE of P-TV is smaller.

## V. Conclusion

In this paper, a P-TV algorithm based on TV algorithm and the theory of polynomial acceleration is prompted. The experimental results showed evidence that the algorithm is effective and stable. And the most prominent advantages of this algorithm are the rapid convergence speed and the less time consuming. This algorithm can be applied to 3D CT configurations without or with small modifications.

*Abstract*— **To diagnostic vary CAN bus based network, an unified customizable diagnostic measure is introduced. The measure is based on customizable RPN format protocol expression and CAN UDS, support most of CAN bus based network. Not only decoding or other normal diagnostics are supported, but also network activity is analyzed, too. Furthermore, the design of customizable diagnostic software is given.**

***Keywords-UDS;RPN;CAN bus Diagnstics;ISO 14229***

## I. INTRODUCTION

CAN based fieldbuses have been used for years and different upper application protocols were produced, such as CANOpen, ISO Bus, SAEJ1939 and DeviceNet, and so on. To apply and maintain those fieldbuses, protocol analysis tool are overwhelming needed. Early detection of network failures and performance degradations is a key to rapid fault recovery and robust networking [1]. Though fieldbus mentioned above are based on CAN bus, the great gap between their application layer make it was very difficult to diagnostic all of them in one application platform. Automotive network ECU manufactured by different vendors is different [2], so a unified customizable diagnostic tool is important to auto diagnostic, too.

CANOE or other software can do this job but the huge invest and not very clearly decode explains are the fatal weakness. There are vary diagnostic tools exist in the CAN bus application. Different diagnostic tools lead to more development and maintenance cost, and for some scenes it is too inconvenient.

In road vehicle application scope, a series of Unified Diagnostic Services (UDS) standards have been made by ISO, its purpose is to make diagnostic more convenient and less development repetitious. ISO 15765 and ISO 14229 have achieve CAN based UDS[3], there should be only one diagnostic protocol theoretically, but it is applied almost only in vehicle area in fact. The CAN based UDS most likely can be used in vehicle-related application scenes.

A CAN based customizable diagnostic method (CCD-Measure) is introduced in this article, furthermore, a customizable diagnostic tool aim on CAN based fieldbus is realized. This CAN bus based customizable diagnostic tool (CCD-Platform) support ISObus, SEAJ1939[4][5], CAN UDS, etc., the most significant is customizable application layer analysis function. Any CAN based protocol nevertheless normal or private can be decoded, explained and analyzed well. Only if a clear definition is provided.

## II. UNIFIED DIAGNOSTIC MEATURE

CCD-Measure introduced in this article is customizable and support CAN UDS, the former make it is possible that CCD-Platform can be used in non-vehicle area such as CANOpen, DeviceNet, meanwhile the latter make sure that most newly designed road vehicle ECU and network can be analyzed and diagnosed by this platform.

### *A. CAN Bus based Unified Diagnostic Services*

CAN UDS is proposed in two related standards, ISO 15765 and ISO 14229. It is designed for road vehicle diagnostics, but it can be used in other area such as farm machinery, construction machinery, etc. Some ECU (electronic control unit, a control device on vehicle bus) manufactures has support the CAN UDS such as Bosch, Perkins and so forth. CAN UDS is an independent upper protocol, support 25 services including “ECURese”t, “TesterPresent” and “ReadDataByIdentifier”, etc. ISO 14229 is an “application layer” in the UDS architecture and ISO15765 part 3 is a simplify version of ISO 14229, both of them define the diagnostic services.

TABLE I. CAN UDS & RELATED OBD[3]

| OSI model | CAN UDS | OBD |
|---|---|---|
| Application Layer | ISO15765-3/ISO14229 | ISO15031-5 |
| Presentation Layer | N/A | N/A |
| Session Layer | N/A | N/A |
| Transport Layer | N/A | N/A |
| Network Layer | ISO 15765-2 | ISO 15765-4 |
| Data Link Layer | ISO 11898-1 | ISO 15765-4 |
| Physical Layer | ISO 11898-1 | ISO 15765-4 |

As Shown in table 1, ISO 15765 support both CAN UDS and old OBD diagnostic method, OBD mean “On Board

Diagnostic", it was a legislated measure for road vehicle diagnostic. In this article we concern about CAN UDS only. The CAN UDS has no Presentation layer, Session layer and Transport layer, both data link layer and physical layer make use of ISO 11898 which is CAN bus international standards.

ISO 15765 part 1 is a general specification for whole CAN UDS, it introduces remain parts of CAN UDS and gives some important concept in CAN UDS such as architecture and related standards. Part1 shows the overview and relationship of different parts. ISO 15765 part 2 gives a general specification of UDS network layer, which was used to diagnose device across different network, such as from power train bus to implement bus. Both single frame (non-segment frame) and multiple frames (segment frame) are introduced. SF is used to report some immediate error code and if one frame is not sufficient for the message, it will be divided several different frame and send under the Flow Control Mechanism's control. To the residual error codes it needs to be report in multiple frames, as shown in figure 1.

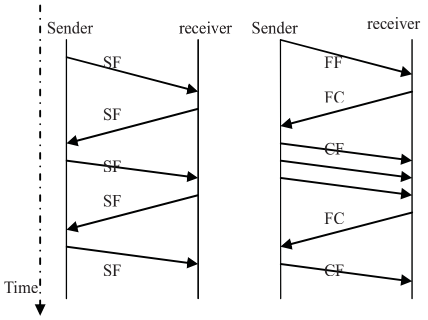

Figure 1. Single Frame and MultiFrame

ISO 15765- part 3 is a simplified ISO 14229, more detailed information is described more clearly in latter. It is a core part of CAN UDS, most application services used by diagnostic are produced in this part. As mentioned early, there are mainly 25 (in ISO 14229 25, ISO 15765 24) services of diagnostic, can be divided into diagnostic and communication management functional unit, data transmission functional unit, stored data transmission functional unit, I/O control functional unit and upload/download function unit. ISO 15765 part 4 describes the OBD diagnostic requirement and it is useless in CAN UDS.

### *B. Choosen Essential Parameters of Customizable Measure*

As mentioned above, a customizable diagnostic measure is introduced and not only for road and non-road vehicle but also for automation application such as DeviceNet, CANOpen, etc. CAN based customizable diagnostic measure (CCD Measure) make use of XML to customizable information. The customizability is based on formal method[7][8]. Although fingerprinting[7] is an useful information, but in this article it wouldn't be concerned.

A protocol is a series of statutes to transfer data correctly and efficiently. Protocol means "A set of standardized procedures for transmitting or storing data, especially those used in regulating data transmission between computers or peripherals."[7] From the view of analysis and diagnostic, an application protocol can be described in four metrics, as shown in formula (1), a protocol can be defined by Format, Error message, Timing and Action. To perform diagnostic, extra information helpful for analysis is Statistic parameters and Other diagnostic information, as shown in formula (2), where F mean Format, T mean timing, S mean Statistics and OD mean Other Diagnostic parameters.

$$P = \{F, E, T, A\} \tag{1}$$

$$D = \{F, T, S, OD\} \tag{2}$$

Format parameters describe structure information of protocol, such as how much fields there are and how many bytes every fields occupied. Vary protocols may have same identifier but different format or same format but different identifier. To CAN bus (2.0B) based network, there are always 29 ID and 8 bytes data, but the explanation were very different from vary protocols.

An application protocol may have various application protocol data unit (A-PDU), but all of them may have same basic format named Root Format, and other kinds of PUD inherent from the Root Format PDU. The hierarchy diagram is shown as figure 2, the root of all format is named Root Format, which may include some important and basic coding rule, such as CAN ID's explanation, it describes an application protocol's basic structure. Level1 Format inherent from root format and can be treated as a "primitive" level, L2 format is service level. The hierarchy between different level of PDU format may achieved by XML.

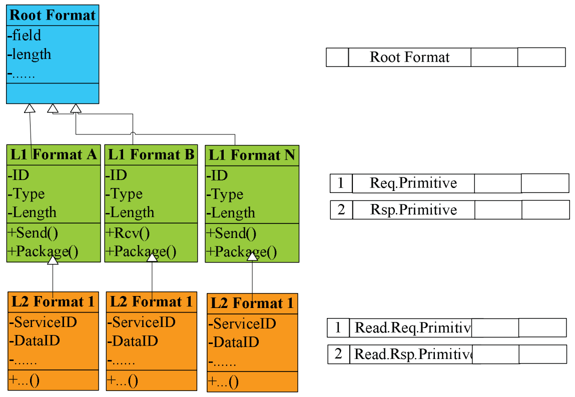

Figure 2. PDU Format Hierarchy

Timing parameters is a time line profile of communication,. When a protocol working, timing parameters describe all the outer activities between different communication peers, which services PDU to be sent, what time and which one response PDU should be sent are defined by timing parameters.

Statistics Parameters are important attributes to diagnostic and analysis of protocol, but not core attributes of protocol definition. Typical statistics parameters are bus load rate, error rate, certain application layer service occurs count, retry count, etc.

Other diagnostics parameters are group of diagnostics parameters which user interested or needed. Those parameters depend on the application protocol to be analyzed. For example, ISO bus has a "Parameter Group Number" (PGN), different

PGN respect some physical value, such as ground speed, wheel speed. Some PGN's occur ratio may be very important for analysis of ISO bus.

### C. Customizable Diagnostic Measure Design

According to (1), and because F, E, T and A are a type of set also, there are the following formulas:

$$\begin{cases} F=\{f_1,f_2,\ldots,f_m\} \\ E=\{e_1,e_2,\ldots,e_n\} \\ T=\{t_1,t_2,\ldots,t_n\} \\ A=\{a_1,a_2,\ldots,a_n\} \end{cases} \quad (3)$$

To illustrate what are "F, E, T, A" look like exactly, a SAE J1939 basic profile is given following as an example. SAE J1939 is a supported protocol by this tool and basic PDU format of SAE J1939 is given as follow picture.

| Priority :3bits | Dp: 1 | Reserved:1 | PDU Specification:8 | PDU Format:8 | Source Addr:8 |
|---|---|---|---|---|---|

Figure 3. Basic pdu format of SAE J1939

As figure.3 shown, a pdu format concerned field type, field name, field length, and so on. Filed name can be treated as variables, such as pri (priority), dp (data page), length can be handled as coefficients, such as 3, 1, etc. According mentioned above, figure3 can be translated an algebraic format as $f_1$, formula (4). Formula (4) $e_1$ is an "error" element of E formula (1), which means negative acknowledgement with error code "-1" and address "error_addr". Formula (4) $t_1$ means a request primitive can be responded by a response primitive.

$$\begin{cases} f_1 = 8*pri+1*dp+1*r+8*pf+8*ps+8*sa \\ e_1 = -1*ack*error\_addr \\ t_1 = 100 \\ a_1 = req+rsp(0) \end{cases} \quad (4)$$

This formula will be converted into RPN (Reverse Polish Notation) to deal with computer conveniently. The transform will be done by computer program, thus the xml input would look like formula (4), but latter will be changed into RPN format.

$$\begin{cases} f_1 = 8pri*1dp*1r*8pf*8ps*8sa*+++++ \\ e_1 = -1ack*error\_addr* \\ t_1 = 100 \\ a_1 = reqrsp0*+ \end{cases} \quad (5)$$

Formula (4) and (5) shows a little part of prime definition of protocol SAEJ1939. The $f_1$ is an algebraic form of figure3 PDU format.

Protocol system fault detection is often conducted by active testing [9] and action analysis. To diagnose the network and each node more clearly, three sets are made, they are normal set, abnormal set and error set. Normal set includes protocol information provided by formula (1), at last it will turn into RPN format like formula (5). Normal set can be predefined by user, it is easy to develop vary protocol's RPN definition according mentioned above. When RPN format protocol definition has been fulfilled, empty abnormal set and error set should be established meanwhile. When it is first run, all traffic on the net work should been captured and analyzed according to RPN protocol definition in normal set. If the traffic is consistent with normal set $P_1$,$P_2$, or $P_i$, it should be a "right " or "normal " action, otherwise, it is an abnormal or error action and the action will be put into abnormal set. An abnormal action will be treated as error action only when user made it. Both abnormal set and error set can be preserved for future. Normal, abnormal and error sets' relationship is shown in following picture.

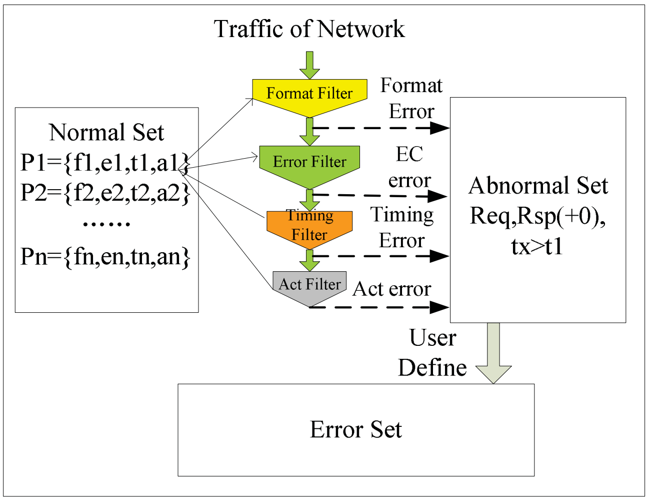

Figure 4. Normal , abnormal and error set

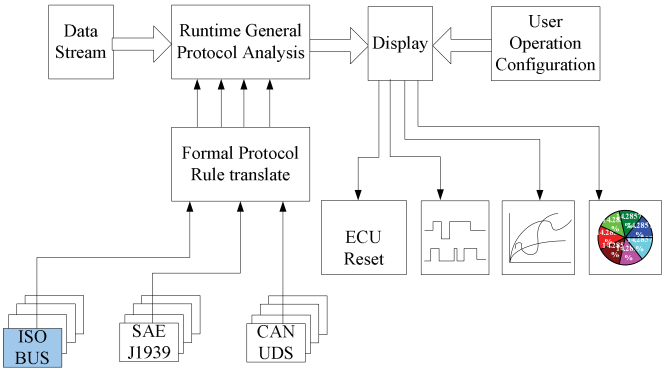
As figure.4 shown, traffic of network will be analyzed according to rules of normal set, compare with $P_i$ (i=1…n) until match or finish, if $f_i$, $e_i$, $t_i$ or $a_i$ is not matched, compare with $P_{i+1}$ , if three of four elements are matched but still not all matched with $P_i$, put it in abnormal set with $P_i'$ (an abnormal $P_i$) otherwise put it as a new element. If user picks up an element of abnormal set and let it belong to error set, then it will be moved into error set.

Customizable characters are reflected in translate protocol definition to RPN formula approach, by this way any protocol can be defined clearly and easily.

### D. Customizable diagnostic meature model

As mentioned above a protocol's analysis is defined by 4 metric essential parameters named F,T, S and OD. A customizable diagnostic measure model is given in this part. Formal Protocol Rule Interpreter (FPRI) is a core concept in CCD measure, it should take 4 metric parameters namely F, T, S and OD.

Customizability is achieved by the FPRI and some Formal Protocol Describe File (FPDF), according to protocol 4 metrics attributes, there are 4 FPDF configuration files. FPRI translate protocol definition to RPN format like formula (5). The four files and other needed files can describe a certain protocol as well as pre-programmed one. FPRI read and interpret the former files to parameters in four metrics, the interpreted parameters are sent to runtime general protocol analysis. The runtime general analysis handle unpackaged raw data stream and explain PDU to physical information. Explained PDU and corresponding physical information are sent to display model, by which list physical information of PDU, unpackaged PDU data, timing information, statistics information and diagnostic information, as shown in figure 5.



Data Stream
Runtime General Protocol Analysis
Display
User Operation Configuration
Formal Protocol Rule translate
ECU Reset
ISO BUS
SAE J1939
CAN UDS

Figure 5. Customizable diagnostic measure mechanism flaw

Runtime general protocol analysis module is responsible for semantic retrive, which means data mapping to semantic. The physical and diagnostic information are created online according to runtime created semantic interpretive rules (according to configure file FPDF). User operation configuration module provides a configuration interface to user, by which operator may decide what kind of data should be displayed and how to do it.

## III. The Design of Unified Diagnostic Platform

A customizable unified diagnostic platform consist of definitions, specifications, data structures, program modules and inter relationship between them.

### A. *The Architecture Design and Analysis*

This platform can be divided into the following parts: CAN bus access device, basic software module, application software module. KVASER leaf light acts as CAN bus access device, cause of it is minimal in physical size and has sufficient supports for developer. Basic software is consisted of driver module, formal protocol rule interpreter, the application module include runtime protocol analysis module, display module and user configure module. As shown in figure 4, the platform is divided into several parts.

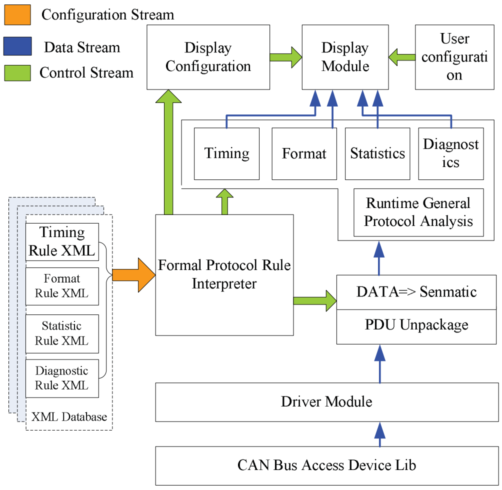


Figure 6. Unified Customizable Diagnostic platform's model structure

As figure 4 shown that blue lines means "data stream", data stream comes from CAN bus and process step by step in our platform and become into some analysis/diagnostic data finally. Salmon pink lines means "configuration stream", those configuration come from user defined FPDF described by XML, in which timing, format, statistics and diagnostics restrict are given. Meanwhile the green lines mean "control stream", the control information define related module's activities.

CAN bus access device lib and driver module provide an interface to access real CAN bus, by which data from CAN bus were captured in time. They are the glue between CAN bus access hardware and the upper application.

Formal protocol rule interpreter is respond to interpret FPDF XML to computer program, the source is formatted nature language or diagnostic formula, and the destination is computer program or corresponding parameters. Formal protocol rule interpreter take one input and produce three output streams.

XML data base including four kinds of FPDF, it provide rule staff to formal protocol rule interpreter.

### B. *Platform Software and Its Deployment*

This software platform is developed by C++ builder and EVC, the CAN bus access tool is KVASAR leaf light. The software's interface is shown as Figure 7.

The platform software can decode and diagnose different CAN based protocol concurrently, as figure 7 shown there are three kinds of protocol named SAEJ1939, ISO Bus and UDS are decoded, analyzed and diagnosed. These three protocols have same root format, meanwhile there are some differences at format hierarchy level 1 and level 2 (figure2). The platform software has decoded J1939 TP.DT, UDS SF and UDS FF frame. The left top area gives a detail diagnostic of UDS, the left middle area decoded SAEJ1939-73's diagnostic information. Because of CAN based protocols have same root PDU format, the decoding and diagnostic program can be integrated together.

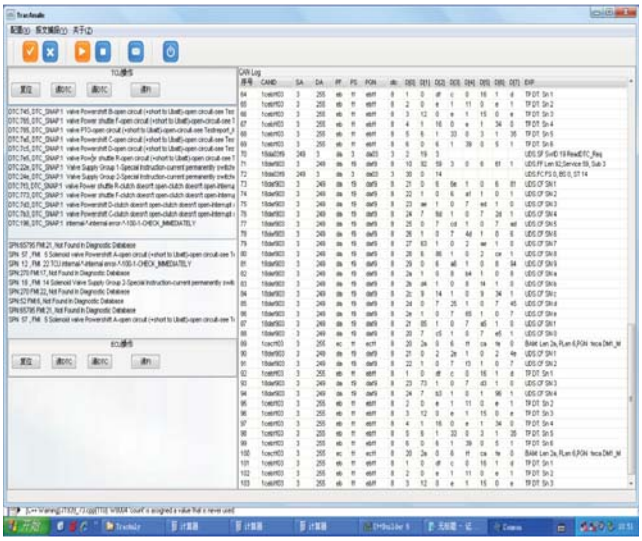

Figure 7. CAN based Customizable diagnostic Platform

The Platform software can be easily applied in Tractor to diagnostic, the application approach is shown as following. Both PC and Wince embedded devices can be make use of.

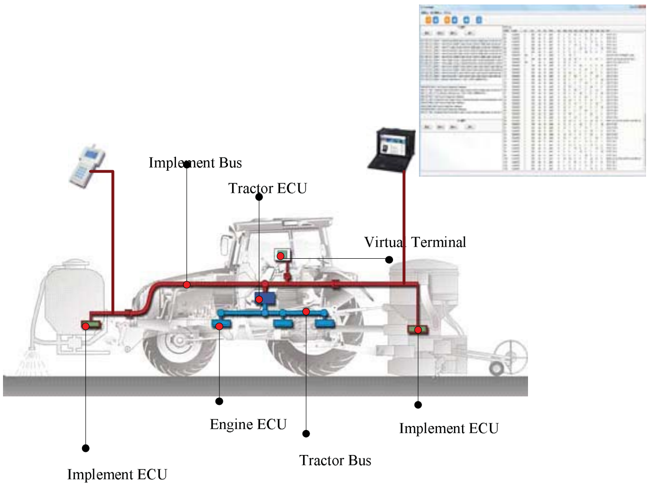

Figure 8. CAN based Customizable diagnostic Platform

The Platform software is applied in 200 horsepower wheeled tractors and 300 horsepower wheeled tractors of YTO Group Corporation, which was biggest tractor and argiculture machine manufacture in China.

## IV. The Design of Unified Diagnostic Platform

A customizable diagnostic of CAN bus based network analysis and diagnostic platform software is designed and realized. Customizable diagnostic parameters are given, furthermore, a customizable diagnostic measure based on protocol RPN definition is introduced.

This platform software can be defined easily and clearly by user, such as SAEJ1939 and ISO bus or other CAN bus based networks. The platform software not only decode or analysis every frame on network, but also spy every challenge-response communication action. And based on the traffic action statistics parameters, a network status can be defined and provide more detail information to user. This platform software was used at YTO Group Corporation.

## Acknowledgment

This work is supported by the Natural Science Foundation of China under contract 61004068.

*Abstract*—**In China, many traditional industrial processes need to be maintained and upgraded to incorporate new technology development. The paper reports our work in improvement of the traditional dyeing process using advanced network control technology. Based on a dyeing industry, we designed the network system of dyeing equipment using industrial Ethernet & Multi-bus technology. The system takes three-level structure: factory management level, workshop control level and field equipment level. Field equipments comprise some PLC and frequency conversion control systems; workshop level adopts two Siemens PLC to centrally control field equipments; HMI, monitoring room PC and remote office PC monitors and manages workshop control level. The network system has multi-stage monitoring, access control and remote alarm functions, realized management - control integration.**

***Keywords-dyeing equipment; industrial Ethernet; Multi-bus technology; network system***

## I. INTRODUCTION

With IT network technology flying, "one network to the end" industrial system constructed by field bus and Ethernet makes factory senior management personnel can obtain the process information of production directly, realizing highly integration of factory management and production[1]. Dyeing industry is one of traditional industries in China; though the automation level of dyeing equipment has greatly increased, but only be single automation equipment, not be network system. In actual production, dyeing equipments of different types and brands are used; it's difficult to realize centralized management and control, adding cost burden to factory unquestionably. Based on the dyeing equipment's present situation of a factory in Qingdao, the paper designed a network system to realize the centralized management and control of production equipments.

## II. NETWORK SYSTEM STRUCTURE

The network system structure comprises field equipment level, workshop control level and factory management level. 1) Field equipment level consists of all original dyeing automation equipments in the factory, including a set of batching equipment for dye ingredients, a set of wax printing machine, three sets of rotary screen printing machine and a set of variable frequency ventilation equipment. Siemens S7-200 CPU226 is the controller of batching equipment; rotary screen printing machines' controllers all are Siemens S7-200 CPU224; the wax printing machine uses Delta PLC of DVP - ES series as controller; and ventilation equipment's controller is Siemens MicroMaster420 inverter. 2) Workshop control level consists of two Siemens PLC, realizing the configuration control of field devices. 3) Factory management level uses monitoring room PC, office remote PC and on-site HMI to achieve data acquisition, management and monitoring of control units in the workshop level. The hardware structure of network is shown in Fig. 1.

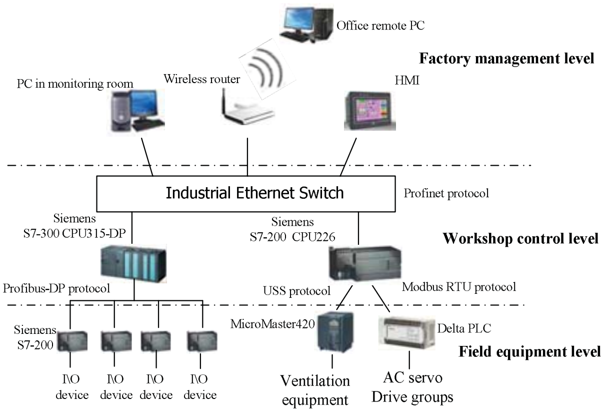

Figure 1. Structure of network system

This network system uses industrial Ethernet and Multi-field bus technology, as shown in Fig. 1. Industrial Ethernet is used for communication of factory management level and workshop control level, and fieldbus is used for communication of workshop control level and field equipment level. For the different control units adopted by dyeing equipments, meanwhile considering equipments' placement, the two sets of S7 PLC are used to realize centralized configuration control of all dyeing equipments in field level. One controller is Siemens S7-300 CPU315-2 DP, which communicates with the batching equipment and rotary screen printing machines using Profibus-dp protocol, form master-slave communication mode. Another controller is Siemens S7-200 CPU226, which communicates with the controller of wax printing machine using the USS protocol, communicates with the controller of variable frequency ventilation equipment using the Modbus RTU protocol.

## III. THE INDUSTRIAL ETHERNET AND FIELDBUS

In the system, factory management level communicates with workshop control level via the PROFINET protocol, which has 100Mbit/s high ethernet transmission speed of IEEE802.3u standard, real-time response time of 10ms, meanwhile can communicate with computer using TCP/IP protocol, the transmission distance reaching 1.5 km [3].

According to different communication functions of control units of dyeing equipments, in the communication of workshop level and field level, the network system adopts Profibus-DP protocol, USS protocol and Modbus RTU protocol. 1) Profibus-DP protocol is based on open Profibus industrial field-bus and an international standard bus used for workshop level and field level. Its transmission speed is 12Mbit/s; its response time is about 1ms. And the interface uses RS-485 mode and shielding twisted-pair cable. 2) USS protocol, which based on serial bus, uses master-slave communication mode, has low hardware cost and reliable message format, and meanwhile includes flexible data transmission. The protocol is suitable for communication of Siemens S7-200 PLC and MicroMaster420 inverter. 3) Modbus RTU protocol, which has become a general standard in the field of industrial control [4], also uses RS485 twisted-pair cable as communication medium. Siemens and Delta PLC both support Modbus RTU protocol, so it is chosen as the data transmission protocol between the S7-200 CPU226 and the DVP-ES series PLC.

## IV. NETWORK SYSTEM COMMUNICATION

### A. *Industrial Ethernet Communication Network*

The system has five industrial Ethernet stations, which use the Ethernet switch's RJ45 interface to communicate with each other. Every station of the system has its own IP address according to local LAN segments. Hardware configuration and IP address of every station are shown as in table I.

TABLE I. HARDWARE CONFIGURATION OF ETHERNET NETWORKS

| **Ethernet station** | **Connecting hardware** | **IP address** |
|---|---|---|
| Office remote PC | Wireless router | 192.168.68.10 |
| Monitoring PC | Ethernet card | 192.168.68.11 |
| HMI | Ethernet interface | 192.168.68.12 |
| Siemens S7-300 | CP341 IT module | 192.168.68.13 |
| Siemens S7-200 | CP243-1 module | 192.168.68.14 |

The Ethernet switch adopts Siemens SCALANCE X208, which has eight RJ45 interfaces. According to the IP address in the data frame from the sending station, the switch determines which station should accept data. Data transmissions of each group are mutual shielding. In online communication, the switch firstly sorts data, then gives the mapping of orders, and finally data exchanges through the internal mechanism.

In factory management level, remote PC and monitoring PC use Wincc6.2 configuration software as platform, which set different access to operate the two PLC in workshop control level. The HMI adopts MT8070iH touch screen, and using touch screen to communicate with PLC in workshop level, the operators can get the dyeing equipment production information easily and achieve three levels management of equipments.

### B. *Profibus-DP Communication Network*

S7-300 PLC communicates with the four sets of S7-200 PLC, forming the structure of a master and four slaves. In the system S7-200 CPUs are all mounted EM277 intelligent communication module, communication rate adapting by itself. As slave station, EM277 accepts data from I/O configuration of master station S7-300. Master station can directly read or write data from S7-200 storage area.

The design process of profibus-DP network configuration is shown in Fig. 2.

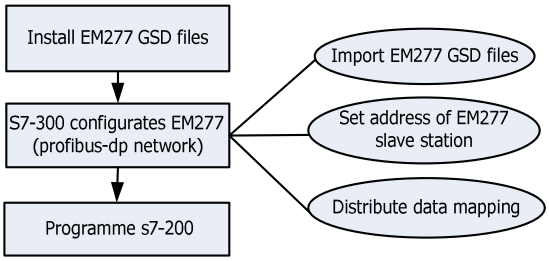

Figure 2. Flow chart of profibus-DP network configuration

After hardware are configured as shown in Fig. 3, the configuration information should be downloaded into S7-300 CPU module. When the four sets of S7-200 slave stations communicate with S7-300, both sides read or write data from the memory of master-slave data mapping (as shown in table II), and realize two-way communication.

| Batching equipment | 6 | VB560～VB575 | IB24～IB41 QB24～QB41 |

### C. *Communication program of Modbus RTU protocol*

Modbus protocol is located in the second floor of the OSI model and a main-slave protocol, which has only one master station in serial bus, adopts the way of request-response communication. The main station sends a string data involving slave station's address. Only the main station can start the Modbus communication. Slave stations don't send data before receiving the main station's request, also slave stations won't communication between each others.

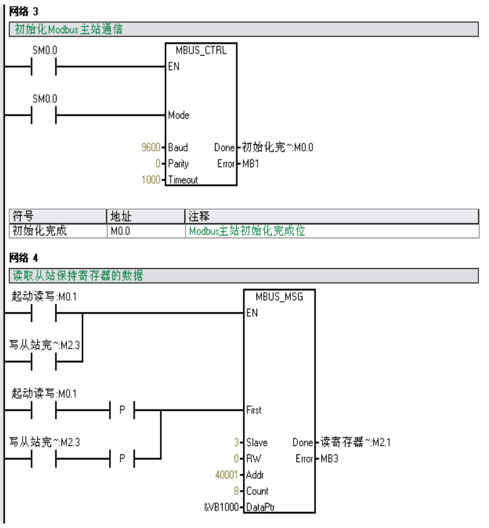
As the master station, S7-200 CPU226 communicates with Delta PLC of the wax printing machine through own Port0 on Modbus RTU protocol. Useing Modbus RTU master instruction in STEP 7-Micro/WIN V4.0 SP5, the digital quantity, analog I/O and holding registers from Delta PLC can be read and written. Before programming, order library should be added and the instruction for calling "Modbus Master Port0" should be chosen. Because the Port0 is taken up by the master station of Modbus, it is set as free port communication mode.

The basic structure of Modbus RTU communication frame is shown in Fig. 4. The slave station address is from 0 to 247 in the frame. The slave address and function code both stand one byte, the starting address and CRC both stand one word in command frame. Data uses word as the unit, high byte in the front, low byte at last.

| Station Address | Function Code | Data 1 | … | Data n | CRC Low Byte | CRC Hight Byte |
|---|---|---|---|---|---|---|

Figure 4. The basic structure of Modbus RTU communication frame

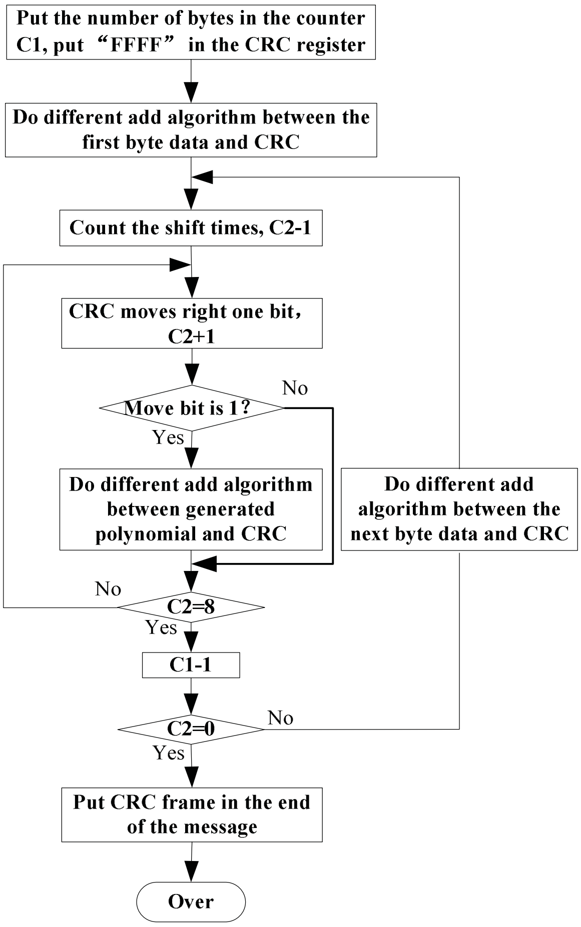
Part of the Modbus RTU communication program code is shown as in Fig. 5:



| 符号 | 地址 | 注释 |
|---|---|---|
| 初始化完成 | M0.0 | Modbus主站初始化完成位 |

Figure 5.  Part of communication program of main station of Modbus RTU

In the Modbus RTU communication, the most important design is the calculation of CRC yards. The CRC data in message are regarded as a continuous binary number, and the most significant bit is sent first. The message data move left by 16 bits, and then are divided by generated polynomial $x^{16}+x^{15}+x^{2}+1$ (the corresponding binary digits is 2 # 1000 0000 0000 0101), the remainder which has 16 bits is the CRC code. It will be attached to the back of message and be sent together. If the process of transmission has no mistakes, the receiving message should be able to be divided with no remainder by the generated polynomial. If happens CRC mistake in the process of transmission, PLC will give up the message data and transmit again. The CRC calculation flow is shown as in Fig. 6.



Put the number of bytes in the counter C1, put "FFFF" in the CRC register
Do different add algorithm between the first byte data and CRC
Count the shift times, C2-1
CRC moves right one bit, C2+1
Move bit is 1?
No
Yes
Do different add algorithm between generated polynomial and CRC
Do different add algorithm between the next byte data and CRC
No
C2=8
Yes
C1-1
C2=0
No
Yes
Put CRC frame in the end of the message
Over

Figure 6. Calculation flow chart of the CRC

### *D. Communication program of USS protocol*

The master station of S7-200 CPU226 uses the USS protocol to communicate with Siemens frequency converter of ventilation equipment through Port1

In the process of controlling frequency converter MicroMaster420, the main program calls communication procedure in S7-200 CPU226 to communicate with the MicroMaster420. Communication hardware consists of twisted pair and built-in RS485 communication interfaces of PLC and frequency inverter. The instructions of USS protocol are used ccording to the following steps: 1) Code user program. After installing Siemens order library, call control order in "USS Protocol Port 1"; 2) Distribute storage area for order library of USS protocol. In the frame of "storage area of library", set starting address for storage area; 3) Set communication parameter. Set communication parameter for the frequency inverter through the MicroMaster420 operation panel, to keep baud rate and address of slave station consistent with that in the user program. Part of the USS communication program code is shown as in Fig. 7.

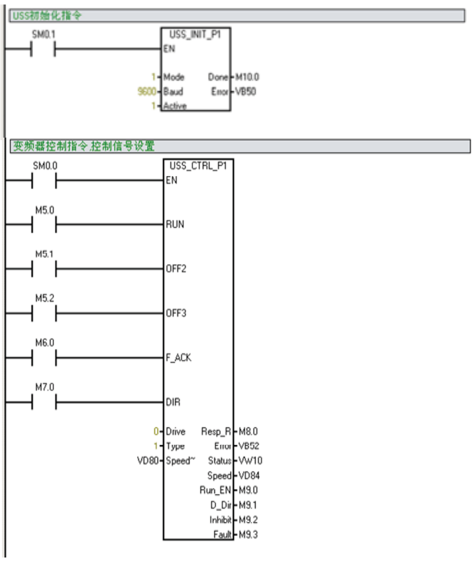


Figure 7. Part of USS protocol communication program

In the software program, most attraction should be put on the design of initial instruction USS-INIT and frequency inverter control instruction USS-CTRL. The initial instruction is used to allow, initialize or prohibit the communication of Micro-Master frequency inverter. The directive can set up communication protocol type and baud rate, activate the corresponding inverter. USS-INIT instruction must be first carried out successfully before other instructions, set “Done” after the instruction completion, and then can continue to carry out other instructions. Inverter control instruction USS-CTRL is used to control the Micro-Master frequency converter which is active. Each converter can only use one such instruction. This instruction puts user commands in a communication buffer. If one frequency converter appointed by "DRIVE" is just right selected by "ACTIVE" parameter in the USS-INIT instructions, the user commands in buffer will be sent to the inverter.

## V. CONCLUDING REMARKS

This article mainly aims at present situation of automation dyeing equipment in factory, designs the network system of three layers communication structure with industrial Ethernet and multi-field bus technology, realizing the integration of equipment management and control. The experiment proves that this system provides a good platform of manufacturing management and monitoring for enterprise management personnel, promotes the management level and production efficiency, and reduces the cost of factory management. The paper provides a feasible technology route for network design of production equipment in industrial control field.

*Abstract*—**In this paper, Linux-RTAI and Matlab/RTW is used to develop real-time control system for fast real-time simulation and implementation of the control algorithm. The hardware of the controller is based on PC/104 cards under Linux-RTAI operating system. The main characteristic of Matlab/RTW is that it can automatically generate the real-time simulation code for many target processors. The combination of Linux-RTAI as a controller platform and Matlab/RTW as control algorithm development environment brings the two main advantages: hard real-time capability and reduced time for control development. Moreover, online signal monitor and parameter modification is realized on the whole structure system. At last, the minimum execution time of real-time control task is determined and the application of real-time control system into flight vehicle is achieved in the work.**

***Keywords-RTAI; real-time; Matlab/RTW; PC/104; controller***

## I. INTRODUCTION

With unceasing consummation and development of control theory and computer technology in the field of automation, real-time capability is the important guarantee to realize the designed control algorithm. Real-time systems are those that can support the execution of applications with time constraints [1]. Basically, real-time systems are classified into two categories: hard real-time and soft real-time. In a hard real-time system, deadlines cannot be missed and the success depends on the task execution within deadlines [2][3][4]. Whereas in the soft real-time systems, there is a certain degree of tolerance for missing deadlines[5]. The importance of the deadlines depends on the type of control system.

Hard real-time control requires a software platform that guarantees certain time constraints. Real-Time Operating System(RTOS) should meet the basic requirements including predictability, pre-emptability, support for multi-threaded scheduling, concept of priorities, and resource sharing mechanisms avoiding priority inversion. Today, there are many available RTOS applied on the market, such as VxWorks[6],uCos[7],QNX[8] and Windows CE[9],etc., while the RTOS based on Linux are gaining attractions due to its robustness and open source code. And researchers, developers, and programmers prefer Linux as the open platform when developing applications. Based on the Linux kernel, RTAI was developed as a real-time operating environment solution at Dipartimento di Ingeneria Aerospaziale Politecnico di Milano (DIAPM) [10].It extends the Linux kernel with hard real-time functionality in addition to allowing the use of all standard Linux drivers and applications. Compared to the commercially available real-time OSs, The RTAIs performance is very competitive with the best commercial RTOSs. RTAI is open source and free under the terms of the GNU. So all needed software can be freely downloaded on the web during the building of the real-time control system.

Moreover, the diversity of control algorithms and development cycle of the projects are very important for engineers and researchers to develop and design every control project. Matlab, which stands for Matrix Laboratory, is an easy-to-use and powerful software for simulation aid design and technical computing. It not only provides Matlab language but also other application program interface to programming languages such as C, C++ and Fortran. Simulink is a graphical toolkit for modeling and simulation which can carry out many simulations of many aspects such as electronics, control engineering and signal processing. The Real-Time Workshop (RTW) provides a C code generator environment for rapid prototyping and development [11][12][13]. It generates source code from Simulink models to create real-time applications, which can operate in PC, ARM, DSP, PC/104, PLC and other hardware systems[14].

Therefore, combining Linux/RTAI and Matlab/RTW, one real control system is established in our project in order to realize hard real-time capability and a rapid development.

The remainder of this paper is organized as follows. The next section presents structural description of the whole real system. Section 3 presents the process of designing real-time controller. Section 4 presents software configuration and development on Windows PC which can implement automatic code generation and transplant into control application. Experimental results and conclusion are given in last two sections.

## II. SYSTEM ARCHITECTURE

978-1-4673-1560-9/12/$31.00 ©2012 IEEE

The whole system structure includes mainly two parts, one is the real-time control system comprised by hardware and software which can provide the run-environment for real-time task execution, the other is the virtual simulation environment composed of computers and related software. The system structure is shown in Figure 1. PC is the core of the design of control block diagrams and automatic generation and compilation for C code, which have Matlab, Simulink, virtual machine and other related software environment. The objective of PC focuses on how to produce and download executable program applicable to the target computer (real-time control system). The target platform is the RTAI target run-time environment. It uses embedded industrial controlling computer PC/104 as real-time controller, which is responsible for receiving executable code from PC by TCP/IP protocol and data processing of various parameters under real-time environment Linux/RTAI. According to data processing results, it can make decision and produce control information to control the running state of controlled object.

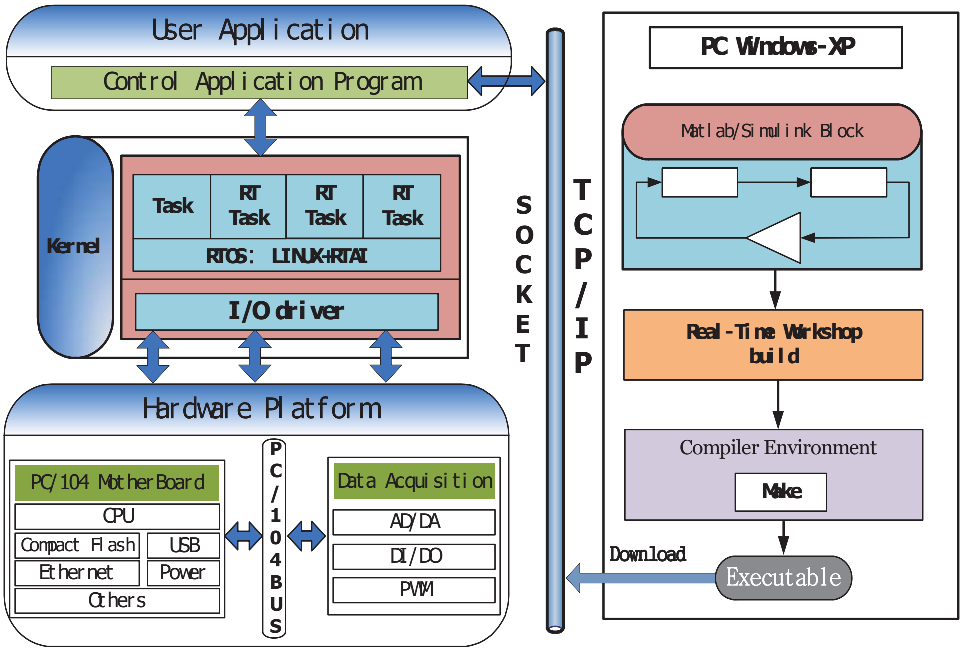

Figure 1. Overall structure

## III. Real-Time Control Target Platform

According to complexity and real-time demands of various kinds of controlled plants, the real controller is developed based on industrial modular design methodology in the following.

### A. *Hardware System*

In order to meet the requirement of a hard real-time environment, boards compliant to the PC/104 standard are chosen as the basis for real-time control system. PC/104 is an industrial control bus, which has some unique features such as small size (96 mm × 90 mm), stack-type connections, low bus drive current and so on[15]. The following two cards utilized in the Linux/RTAI system incorporate the PC/104 bus.

The heart of the hardware system is the CPU card. A PMI2 [16] card manufactured by SBS Science & Technology Co.,Ltd. was selected. The highly integrated CPU board is equipped with:

- Intel Pentium M running at 2 GHz;
- 256 MB of RAM;
- four USB 2.0 ports;
- two serial ports and one parallel port;
- industrial Ethernet interface;
- a CF card socket onboard;
- PC/104 bus.

A PC/104 ADT652 I/O module [17]is added to the stack to implement data acquisition and signal output. The hardware configuration of the card is equipped with the following components:

- 16 analog inputs, 12-bit A/D resolution;
- 100KHz A/D sampling rate;
- 4 analog outputs, 12-bit resolution;
- 24 digital I/O with programmable direction;
- 4 16-bit general purpose PWM ports.

### B. *Software Design*

An important item that allows the use of PC/104 cards in the application of various control algorithms is a real time operating system Linux/RTAI. In the design of the software system, it should include root filesystem, kernel image, TCP

/IP network support, necessary tools and I/O interface drivers. The design process of system software is given below.

*1) Installation GRUB bootloader.*

GRUB is the first software program that runs when a computer starts. It is responsible for loading and transferring control to the operating system kernel software. By using the Grub loader, it is very convenient for booting a GNU/Linux system directly from a CF disk.

*2) Linux 2.6 kernel configuration and filesystem transplantation.*

The new Linux v2.6 offers a host of improvement in the configuration and real-time features compared with the earlier Linux kernel. Therefore, the design chooses Linux 2.6.23 kernel version.

In order to make Linux real-time, the kernel source was patched with the correspondent RTAI patch. In the paper, RTAI version is 3.8 which includes hal-linux-2.6.23-i386-1.12-03.patch for making Linux 2.6.23 real-time. "HOWTO install RTAI"[18] describes instruction on how to configure the Linux kernel and RTAI target in detail.

Building the root filesystem with Busybox involves selecting files necessary for the system to run. Here is a reasonable minimum set of directories for the root filesystem(ext3): /bin, /boot, /dev, /etc, /home, /lib, /mnt, /proc, /sbin, /usr. These directories and files are copied into CF card in reference to “Building a root filesystem” [19].

*3) ADT652 I/O card driver modules including AD, DA, DI, DO, PWM.*

A device driver’s function is to provide access to a piece of hardware and the Linux Kernel provides a stable user space interface or applications. In Linux, device drivers are created as modules of the Linux Kernel that hide the details of how the device works. Each module can be used or removed from the kernel at runtime depending on what hardware is available.

In order to realize data collection control, device drivers for ADT652 card are responsible for analog input signals collection, digital input signals collection, analog output, digital output and PWM signal output. Five modules for ADT652 I/O signals control are designed in C programming, which can be added into kernel dynamically.

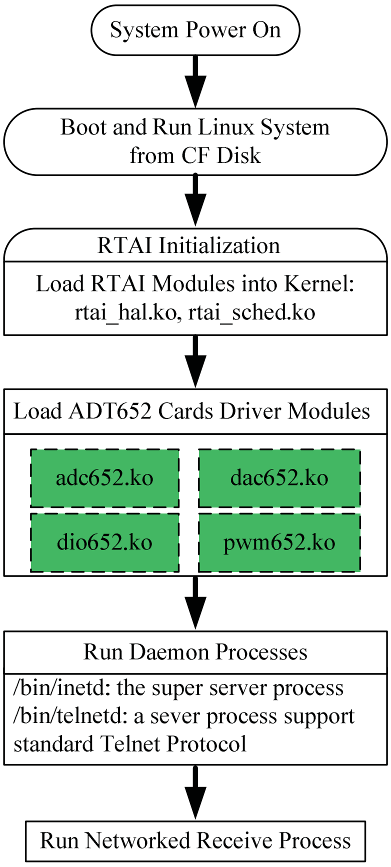
*4) Networked receive programs*

In networked control environment, network configuration and programming for receiving executable files is the important guarantee for target platform to realize communication with the host computer (PC side).

There are three important executable files in the /bin directory for network communication: *inetd*, *telnetd* and *recvn*. The *inetd* daemon is a super-sever daemon that manages Internet services on Linux system and the *telnetd* daemon is a server that supports the DARPA-standard TELNET virtual-terminal protocol. They are started automatically as the system starts up so that it is more convenient for users to login Linux/RTAI system and have remote control and on-line modifying from PC side to target computer.

Networked receive process named *recvn* is designed for receiving executable files generated from Simulink block diagrams by RTW in PC computer via TCP/IP using Socket. After successful receipt, the process creates a child process which executes the generated executable.

Figure 2 below illustrates the program execution flow after the target system starts.



System Power On
Boot and Run Linux System from CF Disk
RTAI Initialization
Load RTAI Modules into Kernel: rtai_hal.ko, rtai_sched.ko
Load ADT652 Cards Driver Modules
adc652.ko
dac652.ko
dio652.ko
pwm652.ko
Run Daemon Processes
/bin/inetd: the super server process
/bin/telnetd: a sever process support standard Telnet Protocol
Run Networked Receive Process

## IV. SOFTWARE CONFIGURATION AND DEVELOPMENT OF HOST SYSTEM

In this section, host PC’s software configuration and development is covered in details. Figure 3 describes the functions of software on host PC when a control project is built. Matlab and VMware Workstation are two necessary software components for the host PC (Windows XP Computer). As mentioned above, Matlab is responsible for constructing the control block diagrams in Simulink and generating C code through RTW. VMware Workstation, which is a kind of virtual machine software, can run various operating system images at the same time. A real-time Linux operating system is installed in VMware Workstation so that it can provide compile environment for converting generated C code into executable file. In host PC, another software named ‘NetConTop’ is developed to have online monitoring of parameters and signals of executable program running on PC/104 target. For details, see [20].Here is the main development process of Matlab/Simulink/RTW and VMware RT-Linux-OS.

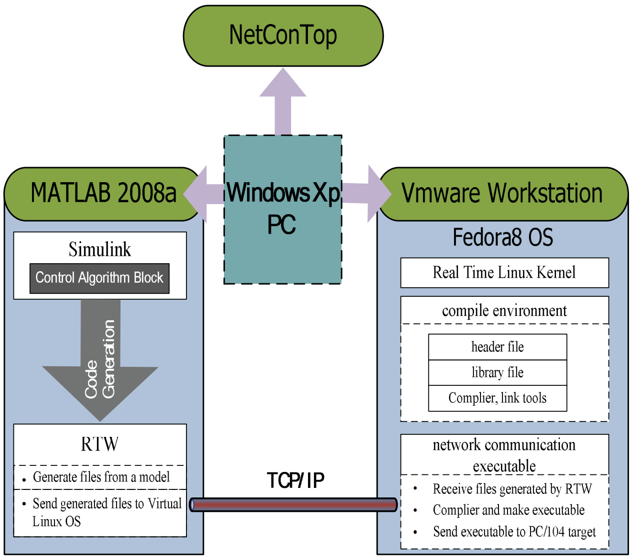

Figure 3. The structure of system software

### A. Matlab/Simulink/RTW

#### 1) I/O Blocks Development

I/O blocks are necessary elements from which real-time models can be built. Simulink enables designers to create custom blocks with C-MEX S-function. C-MEX S-function, which is written in C programming language and compiled as MEX-files, defines block properties and allows users to add desired blocks to Simulink models. In the work, I/O blocks are configured through custom blocks and listed below (Table 1).

TABLE I. I/O BLOCKS

| **Block Name** | **Parameter** | **Port Number** | |
|---|---|---|---|
| | | ***Input*** | ***Output*** |
| ADC | ● Input Channel<br>● Sample Time | 1 | 0 |
| DAC | ● Output Channel<br>● Sample Time | 0 | 1 |
| DI | ● Input Channel<br>● Sample Time | 8 | 0 |
| DO | ● Output Channel<br>● Sample Time | 0 | 8 |
| PWM | ● Output Channel<br>● Frequency<br>● Sample Time | 0 | 1 |

#### 2) Library Files for Code Generation

The process of generating target-specific code is mainly controlled by a target language compiler file and a template makefile. To support Linux/RTAI environment, the target language compiler file named '*grt_pc104.tlc*' is developed to control the way code is generated by RTW and the template makefile named '*grt_pc104.tmf*' is created to generate one right makefile for compile environment on Linux platform.

#### 3) Main Program of Model Files

To obtain real-time model executable, the generated code should be compiled and linked with specific library to one main program. At this point, a main file named '*rtmain.c*' is developed. It includes a main thread and two slave threads. When the executable starts, the main thread initiates the other two slave threads: one starts the real-time control task, the other is responsible for the communication between the real-time control task and the external GUI monitoring software (NetConTop).

#### 4) Files Sending Program

The generated code should be compiled on Linux platform, but Windows is much more popular with most PC users. So Virtual Machine is introduced to create virtual compile environment (Section B will give a detailed account of the process). In this case, a file-sending program named '*sendfilewin.exe*' is designed to send the generated code to Virtual Machine based on Windows Sockets. The command of calling this program is added into '*grt104.tmf*' so that the generated code can be sent automatically by a mouse click.

### B. VMware/RT-Linux-OS

#### 1) Build Compile Environment

VMware Workstation, which is a kind of virtual machine software, can run various operating system images at the same time and get connections to its host or other computers on the network after the right network configurations. Fedora 8, one of the most popular free-as-in-freedom Linux distributions, is installed on VMware Workstation 7.1 running on Windows XP PC host. In order to build complete compile environment, RT-Linux OS is created by using the same methodology as that used in constructing a real-time Linux kernel based on the above Fedora-VMware platform. As necessary files including header files, library files are added into the virtual RT-Linux environment by the way of file sharing, Fedora-VMware system has the ability of compiling and linking the generated code to the final executable file which has the same name as the model file.

#### 2) Network Communication Program

Figure 4 shows data communications among the three components: Matlab, Fedora-VMware and PC/104 target. In Fedora-VMware environment, one network communication program named '*recvfdr*' is designed by using Linux sockets. It has functions in the following:

*a) receive the generated files sent by sendfilewin.exe;*

*b) compile and link main file, generated files and library files together into a single executable file model;*

*c) download the executable model to PC/104 target.*

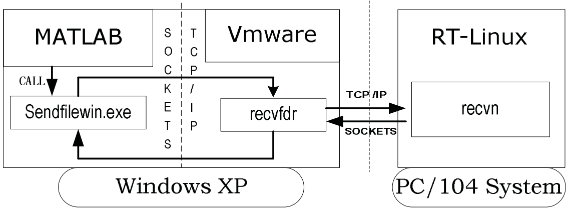

Figure 4. The structure of network communication

## V. APPLICATION EXAMPLE

The following examples illustrate the process during the implementation of a PID closed loop control for a four-wing flight simulator in order to have a hardware-in-the-loop test of one designed real-time control system.

### *A. Matlab Toolbox Testing*

The Matlab version in test is 2008a, and contains totally 804 blocks including Simulink, Control System Toolbox, Fuzzy Logic Toolbox and so on. After the test, there are only 96 blocks failed in the test, and the rest of which can be used in the system well.

### *B. Real-Time Performance Evaluation*

In order to get the minimum execution time of real-time control task, the blocks of DAC and PWM are tested to evaluate the system's real-time performance, and finally the minimum sample period is determined as 18us. As for the medium scale programs, the control task can be finished within one minimum period of 500us.

### *C. Fight-Attitude-Control Experiment*

Figure 5 shows the construction of four-fixed-wing flight simulator system. Two couples of DC Motors as well as gears are fixed on both ends of the beam to drive respective propellers. The motion of propellers can rotate the flight simulator in pitch or yaw. For example, a couple of horizontal propellers can generate a vertical force, causing the flight simulator to pitch up or down. Pitch angle and yaw angle are two important flight dynamics parameters that can be detected by two angle displacement sensors mounted on the pivot and sent to controller unit as the feedback information. Based on the feedback of pitch and yaw angles, the desired controller perform a control signal to motors through a power-expansion circuit in order to realize the attitude control of the flight simulator.

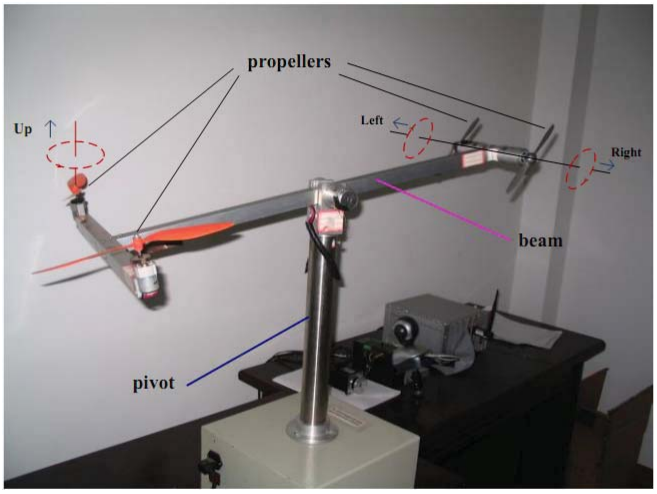

Figure 5. Four-fixed-wing flight simulator

The design and implementation fight-attitude-control system is shown in the following steps.

Step 1 Design a model file including ADC blocks, DAC blocks and other system blocks for both controller and plant in Simulink. In the paper, a PID controller with Loop-up compensator is designed for flight attitude control implementation as shown in Figure 6.

Step 2 Configure IP addresses of VMware and PC/104 target in Matlab/RTW dialog box and start automatic compile and download process by clicking build button.

Step 3 Use NetConTop software to have a monitor of PC/104 controller. In the project of NetConTop, the signals and parameters of the control model can be obtained and tuned with GUI application by users.

Finally, experimental results showed that the entire controller could complete all its tasks within the sampling period of 400 μs. Figure 6 shows the control block diagram and the monitoring interface of flight simulator system.

## VI. CONCLUSION

In order to satisfy the requirement of fast development and hard real-time capability, the paper takes Matlab/RTW and RTAI as software combination, and it realizes the modules imaging, modularization and configuration. The process of hardware and software design for real-time control system is described in details. At last, experimental results show that one control block diagram can complete all of its tasks within the sampling period of 500us and the application into flight vehicle is achieved.

## ACKNOWLEDGMENT

The authors would like to thank the referees for their valuable and helpful comments which have improved the presentation.

***Abstract*—By analyzing the peer classification, structure, and configuration of juxtapose framework (JXTA), a mixed topology in a campus network environment is designed and implemented for peer-to-peer instant communication. A novel method of transmitting video data on JXTA overlap network is proposed, by which video can be included in JXTA applications. The feasibility is proved, furthermore, the performance is tested.**

***Keywords- P2P; video transmision; JXTA***

## I. INTRODUCTION

In recent decades, P2P technology is increasingly used in instant message applications and file sharing systems based on internet. There has appeared many open source or private P2P frameworks provided for developers, by which users can implement their own communication softwares, such as JXTA[1], Self-Chord[2] and [3]. All above frameworks facilitate our developing of transmitting text messages, but they are not convenient to transmitting video. However, Red5[4], another powerful P2P framework, provides both text and video transmission interfaces, it is not widely used restricted by its size of hundreds Mbs.

Considering the raising performance and increasing bandwidth of internet devices, video transmission is not problem any longer for common local PC or even remote PC on wide area network scale. So, a cross-platform P2P instant messaging system with video transmission is quite significant for users.

JXTA, pronounced 'juxta', comes from the word juxtapose, that reflects the operations by which peers establish temporary associations to form a P2P network. Reference [5] shows a method which sends a stream media file via JXTA pipe, it denotes that we can also receive real time video package on JXTA overlap network.

In this paper, we describe how we design and implement the transmission with JXTA version 2.6 comprehensively. It is also applied for version 2.7.

It is quite noticable for JXTA beginners that the URI which is offered by official containing Relay list and Rendezvous list have not worked any more after version 2.5[1]. We should establish our own Rendezvous seed peer and Relay seed peer (if neccessary) on a known IP address, so that our JXTA peer can contact each other via the services provided by them.

## II. PEERS OF JXTA

There are three types of nodes in JXTA framework, edge peer, relay peer and rendezvous peer, they play different roles respectively when JXTA is running.

### *A. Edge Peer*

An Edge peer is nearly the most frequently used peer in JXTA. As a basic JXTA peer, it tries to connect and to remain the connection to one and only one Rendezvous peer. An Edge peer can use both unicasting and multicasting to contact with other JXTA peers. Each communicate mode can be implemented as TCP or HTTP by modifying the configuration file before Edge peer starts. If multicasting is enabled, an Edge peer can communicate with other Edge peers directly on LAN.

### *B. Relay Peer*

A Relay peer is a special Edge peer who has routing ability. We can compare a Relay peer to a router on network. It is needed when a peer with private IP attempts to contact peers from WAN. Typically, a remote peer wants to establish a connection to NATed peer or peer behind firewall, it should try to find a route which can go "through" NAT server or firewall device under the help of Relay peer. It provides means for peers having private IP on a LAN to become reachable. A Relay peer must have a public IP, namely, a private IP is useless for Relay peer.

### *C. Rendezvous Peer*

Rendezvous peers are Edge peers those offer services of JXTA rendezvous for a peer group. A peer group can assimilate to a JXTA LAN, and Rendezvous peer can assimilate to a gateway of this JXTA LAN. So, a peer group should have at least one Rendezvous peer. Edge peers can know each other via Rendezvous peer who performances as the leader of the group. Rendezvous peers accept lease requests from Edge peers and propagate these messages through the peer group to Edge peers.

## III. PEER CONFIRGURATION AND DEPLOYMENT

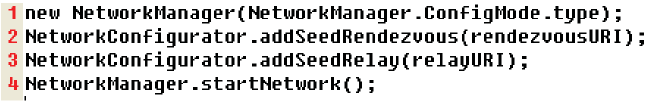
JXTA beginners are always confused for constructing their first JXTA environment, because of their lack understanding of the roles those JXTA peers play. Similarly, we can see different

This work was supported in part by the National Natural Science Foundation of China under Grant 61021002.

type of peers as different network devices with the help of network knowledge. Edge peers work as the common PC in LAN, rendezvous peer can be considered as the gateway PC of this LAN, and we can regard relay peer as the router that makes local peers contact other peers out of the LAN.

According version 2.5 of JXTA and former versions, there was URI http://rdv.jxtahosts.net/cgi-bin/rendezvous.cgi?3 plays the role of default Rendezvous seed. People can use it as a static Rendezvous peer in their own systems. But now, it is not valid any longer. Users need to configure different kinds of peers and deploy them on internet.

If you want to start a peer, at first you should set type of peer, such as Rendezvous or Relay peer, even Edge peer, these codes are given in Figure1.



```
1 new NetworkManager(NetworkManager.ConfigMode.type);
2 NetworkConfigurator.addSeedRendezvous(rendezvousURI);
3 NetworkConfigurator.addSeedRelay(relayURI);
4 NetworkManager.startNetwork();
```

Figure 1. Code of peer's configuration

After the codes on line 1, the seed should be added to the peer you implement, then your peer can communicate with other LAN peers via Rendezvous, even WAN peers via Relay.

These configure operations must be done before you start the JXTA. Once *startNetwork()* method runs, the JXTA framework works. It will cost few seconds to initiate the low layer program.

As mentioned before, different type peers play different roles respectively on JXTA network. For a JXTA application running on LAN, the organization is as simple as shows in Figure 2. All peers on LAN compose the overlap network of JXTA. At least one Rendezvous peer is required to this peer group, and other peers can communicate with each other, for example, using pipes.

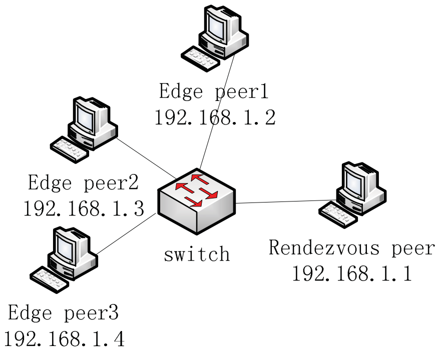


Figure 2. Topology of JXTA overlap network on LAN

But in actual case, only LAN scope is not enough for a more complex application, which peers are required to send and receive data through NAT devices or firewall devices even both of them. In this case, Relay peer works as router to help peers become visible to others, and Rendezvous peer plays a role like gateway to help Edge peers, which connect to it directly, to communicate with other any peers those connect indirectly.

Figure 3 demonstrates a typical topology of JXTA wide area network. A classic mixed structure is adopted to fulfill our design, which contains both peers and server that runs as the register server to let peers logon the JXTA network. Meanwhile, the server is a special configured peer that is not only the Rendezvous, but also a Relay peer.

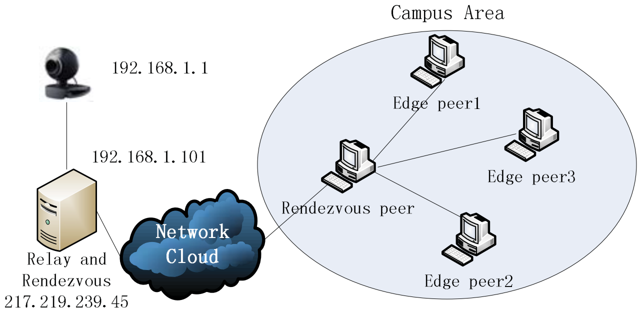

Figure 3. Topology of JXTA overlap network on WAN

## IV. Communication Among Peers

JXTA provides three kinds of data communication methods, singlepipe, bidirectionpipe and multicast socket, whose services are implemented based on TCP socket, and these functions are the most important of JXTA communication.

A singlepipe is a single direction socket pipe. Two participants of singlepipe should possess the same PipeAdvertisement, which is the unique identifier of JXTA pipe in a JXTA network. It means that the later joined peer must know the PipeAdvertisement created by the former peer, namely the PipeAdvertisement needs to be hardcoded in the later joined peer, and data can only be sent from the former to the later.It is quite inconvenient to develop a temporary pipe in the practical programs.

Unlike singlepipe, a bidirectionpipe can send and receive data from either side of the pipe. Contributed by bidirectionpipe, we do not need to create two simple pipes for both side of a data interaction.

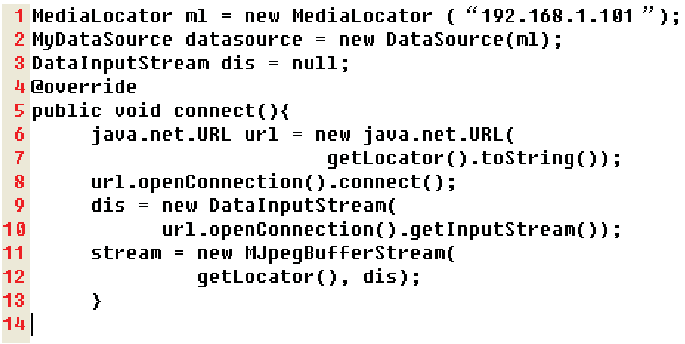
Multicastsocket plays important role in our software, because in many cases data needs to be sent from one peer to many other peers who have the advertisement of this multicastsocket. It is low-performing and inflexible to create many pipes for the data transmission, Instead, multicastsocket is quite appropriate for handling these jobs.

## V. Video Transmission

The working principle of IP camera that we use is to create 30 or less jpeg pictures and to send them each per second by a self-contained web server to browsers of clients via TCP/IP or HTTP links. And our purpose is to transmit these jpeg pictures on JXTA network by sender module below. So, jpeg pictures must be captured first.

### A. Video capture

According to the CGI document provided by IP camera producer, we establish a HTTP connection with IP camera and get the byte stream of jpeg pictures. The code below, in Figure 4 shows how we get data from IP camera.



```
MediaLocator ml = new MediaLocator ( “192.168.1.101 ”);
MyDataSource datasource = new DataSource(ml);
DataInputStream dis = null;
@override
public void connect(){
     java.net.URL url = new java.net.URL(
                         getLocator().toString());
     url.openConnection().connect();
     dis = new DataInputStream(
           url.openConnection().getInputStream());
     stream = new MJpegBufferStream(
              getLocator(), dis);
     }
```

Figure 4. Code of capturing video data from IP camera

As shown above, *ml*, the instance of class MediaLocator, will be set as the media locator in constructed function of class MyDataSource which extends PushBufferDataSource. In the overrided *connect()* method, *getLocator()* method will get the media locator and attach it to url, an instance of class URL. After connecting with url, variant *stream* is filled with class MJpegBufferStream object.

An instance of class MyDataSource is used in class MJpegBufferStream which implements PushBufferStream interface, and *read(Buffer buffer)* method is overrided in MJpegBufferStream class to push data into the parameter—buffer which is used be sent out by JXTA pipe.

### B. Sending and Receiving

After capturing the Jpeg pictures from IP Camera, each Jpeg picture, namely the data in buffer, will be encapsulated as a DatagramPacket object, and sent out via JXTA pipe or JXTAMultiSocket. This sending process is implemented by a single class HttpSender. Then, the peer creates an advertisement that announces its resource, publishes and remote publishes this advertisement on JXTA network, so that other peers can discover it.

Instance of class HttpReceiver takes charge of receiving data of DatagramPacket type one by one from JXTA pipe or JXTA multicastsocket.

### C. Display

One received DatagramPacket data is a MJpeg picture, it will be conducted by JPanelPlayer class which extends JPanel and responses to create a JPanel style player. This player is initiated in class CameraTest and once a picture is retrieved *updateScreen()* method in CameraTest would recall *repaint()* method to repaint the current picture on the JPanel instance. The relationship among all the classes is illustrated as UML diagram below, in Figure 5.

## VI. Example

### A. Enviroment

Table I shows both system and hardware devices information those participate in our test.

TABLE I. Environment of test

| ***Device*** | ***Info*** | ***Peer mode*** | ***IP Address*** |
|---|---|---|---|
| Server | CPU: i7 930 2.8Ghz<br>Memmory:3.25G<br>System:Win XP 32bit<br>BandWidth of Enthernet:100M | RDV and Rendez-vous | 217.219.118.45 |
| IP camera | | none | 192.168.1.101 |
| PC1 | CPU: AMD 640x4 3.0GHz<br>Memmory:3.25G<br>System:Win XP 32bit<br>BandWidth of Enthernet:100M | Edge | 219.217.242.18 |
| PC2 | CPU: AMD 640x4 3.0GHz<br>Memmory:3.25G<br>System:Win7 32bit<br>BandWidth of Enthernet:100M | Edge | 172.17.52.83 |
| PC3 | CPU: Pentium D 3.0GHz<br>Memmory:1G<br>System:Win XP 32bit<br>BandWidth of Enthernet:100M | Edge | 202.118.233.57 |

Environment of test

A server accesses in internet with a public IP 217.219.239.45, and connects to an IP camera with private IP 192.168.1.101 directly. PC1, PC2 and PC3 locate on different network environments that we do not know clearly, and they are all the receivers which are used to test the performance of this video transmission based on JXTA framework. The topology of this example is illustrated by Figure 6.

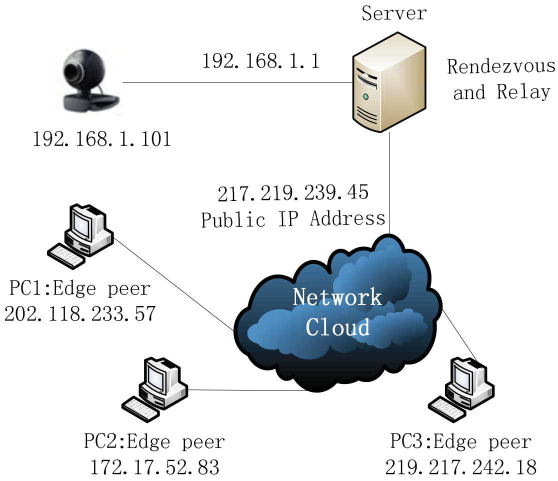

Figure 6. Test topology

## B. *Result*

This software is tested in three different places. It firstly runs on an IP 219.217.242.18 that connects to server directly, After connection established, video is captured by the recerver, and displayed in a JPanel style window that shows in Figure 7.

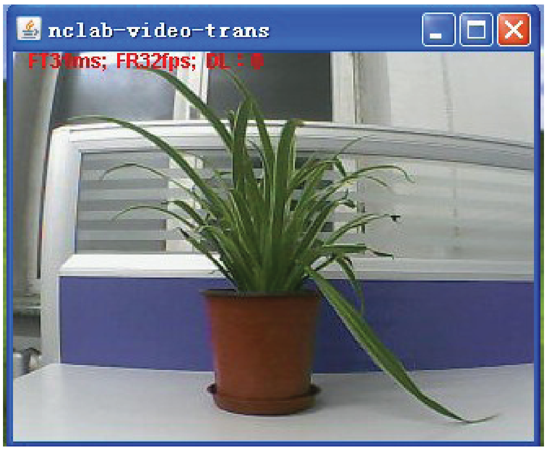

Figure 7. Captured video on IP 219.217.242.18

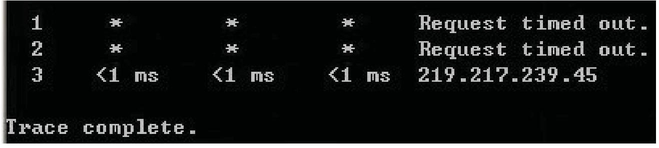
It is a direct connection between client and the server as shown in Figure 8.



```
 1     *        *        *     Request timed out.
 2     *        *        *     Request timed out.
 3    <1 ms    <1 ms    <1 ms  219.217.239.45

Trace complete.
```

Figure 8. Path between 219.217.242.18 and 219.217.239.45

Secondly, we run our application in another laboratory with IP 172.17.52.83, seemingly not in the same network segment to server's IP. The software received video data from server, and showed it by the player, as Figure9.

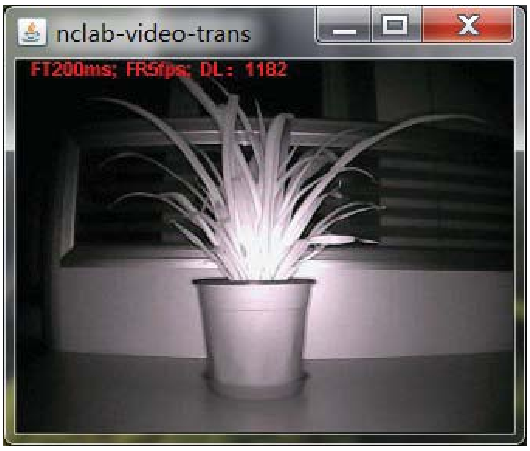


Figure 9. Captured video on IP 172.17.52.83

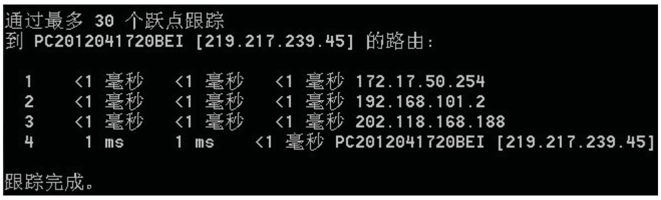
Figure 10 shows that there are four hops between this receiver and the server.



```
通过最多 30 个跃点跟踪
到 PC2012041720BEI [219.217.239.45] 的路由:

  1    <1 毫秒   <1 毫秒   <1 毫秒 172.17.50.254
  2    <1 毫秒   <1 毫秒   <1 毫秒 192.168.101.2
  3    <1 毫秒   <1 毫秒   <1 毫秒 202.118.168.188
  4     1 ms      1 ms    <1 毫秒 PC2012041720BEI [219.217.239.45]

跟踪完成。
```

Figure 10. Path between 172.17.52.83 and 217.219.239.45

Finally, we test it in another campus of our university, and the IP is 202.118. 233.57, seemingly not in the same network segment to the IP of server either, and the data is received, as we can see in a display window of Figure11.

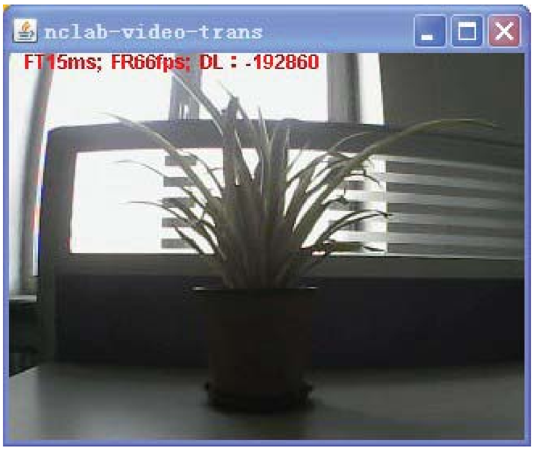


Figure 11. Captured video on IP 202.118.233.57

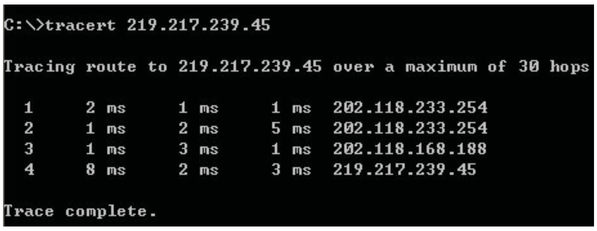
We find the three hops path from the local PC to server. That denotes the data can be delivered crossing different network segment, as shown in Figure 12.



```

Tracing route to 219.217.239.45 over a maximum of 30 hops

  1     2 ms     1 ms     1 ms  202.118.233.254
  2     1 ms     2 ms     5 ms  202.118.233.254
  3     1 ms     3 ms     1 ms  202.118.168.188
  4     8 ms     2 ms     3 ms  219.217.239.45

Trace complete.
```

Figure 12. Path between 202.118.233.57 to 217.219.239.45

That denotes the data can be delivered crossing different network segment.

## VII. Conclusion

The proposed video transmission system achieves sending and receiving video data via internet based on JXTA. It may be quite useful for developers who want to develop their own P2P instant message systems containing real time video image. By analyzing source code of JXT and CGI document of IP camera, we capture the video data from HTTP and divide to individual byte array for each MJpeg format picture. Then JXTA pipe or JXTA multicast socket is created to send them out. Finally, these video data can be received by other JXTA terminals on internet those run as the receiver. For original edition JXTA, for example version 2.7 and earlier releases, only text messages and XML format messages can be used by provided interfaces.

In this paper, we get a simple improvement of transmitting video via JXTA without any optimizing. So, the performance depends on network environment absolutely, this can be inferred indirectly in the result section of this article. As a large scaled application, P2P software should have an optimized structure to enhance its processing ability and increase it efficiency[6][7]. It is the target of our future research.

***Abstract*—The power management strategy can greatly affect the fuel economy of hybrid power systems. This work presents an optimization based power management strategy of hybrid fuel cell power sources during real-time operation. In this approach, local optimization strategy is adopted because it doesn't need the priori knowledge of the future power demand. Every step, the current power demand is measured and the real-time optimal power distribution is determined by maximizing the efficiency of the hybrid system. Simulation and experimental results are presented to show that this real-time power management optimization strategy is feasible and can provide good fuel economy.**

***Keywords*—Fuel cell hybrid, Power management, Real-time optimization**

## I. Introduction

Fuel cell is considered as one of the most attractive power sources with applications ranging from automobiles to stand alone power generation plants due to its environmental-friendly [1], [2]. Among the various kinds of fuel cells, proton exchange membrane fuel cells is one of the promising energy sources due its higher power density, lower operation temperature, quick start up and long cycle life [3]–[5]. However, the dynamics of the fuel cell stack is limited by the air and hydrogen delivery system. A fuel cell only power system may not be sufficient to meet the load demands, especially in peak power demand or transient situation. Other energy storage devices, such as batteries and supercapacitors, are needed to supplement the fuel cell system in application [6]–[8].

In research of the fuel cell hybrid power sources, study of the power management strategy is one of the important tasks, especially in fuel cell hybrid vehicles. Many literatures about power management control strategy, based on optimization, can be found. Brahma et al. [9] used the dynamic programming technique in the optimization of instantaneous generation/storage power split in series hybrid electric vehicles. Delprat et al. [10] presented a global optimization method based on optimal control theory. All of these optimized power management strategies are based on a prior knowledge of the future power demand and not suitable for real time control.

Also, Some literatures studied the real time power management strategies, based on real time optimization. Delprat et al. [11] derived a real-time control strategy from optimal control theory. Rodatz et al. [13] also used ECMS to determine the real time optimal power distribution of a fuel cell/supercapacitor hybrid vehicle.

In general, it is need a priori knowledge of the future power demand to find a global optimal solution of power management. So, global optimization is infeasible in real time power management control. On the other hand, strategies that deal with local optimization are suitable to real implementation. In this paper, a fuel cell/battery hybrid power source is studied and a local optimal power management strategy is presented. The performance of this local optimal solution is compared with that of a optimal fuzzy power control and management strategy that presented in literature [14].

The organization of this paper is as follows. In section II, the structure, characteristics and models of hybrid power sources are introduced. Then, the proposed power management strategy based on local optimization is presented in section III. In section IV, the simulation results are shown and the performance of the proposed strategy is compared with that of other strategies. The experimental results are also reported in this section. Finally, the conclusions of this paper are included in section V.

## II. Hybrid power sources

The fuel cell/battery hybrid power sources combine the high power density of batteries with high energy density of fuel cells. The fuel cell hybrid power sources consist of the fuel cell stack, a battery bank, the DC/DC converter to stable the fuel cell output voltage.

Fig. 1 is represented the proposed topology of the fuel cell hybrid power system. The fuel cell system is connected to the DC bus with a DC/DC converter, whereas the battery bank is directly connected to DC bus passively. As to the load, a AC motor is considered. The current flow to the DC bus from fuel cell system can be controlled by the DC/DC converter, the difference between the current draw from the inverter and the current out from DC/DC converter is compensated by the battery bank. Given a certain load power $P_{load}$, this power

978-1-4673-1560-9/12/$31.00 ©2012 IEEE

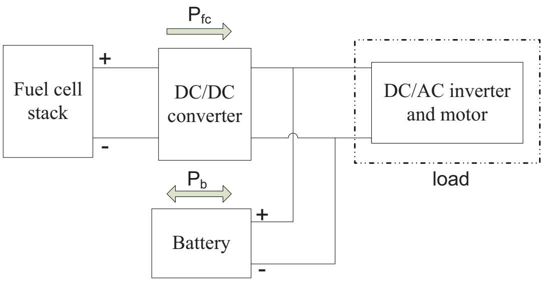

Fig. 1. configuration of fuel cell hybrid power sources

should be supplied by fuel cell system, $P_{fc}$ and the battery bank, $P_b$. At every time, the power balance should be satisfied. That is

$$P_{fc}(t_k)\eta_{dc} + P_b(t_k)\eta_b = P_{load}(t_k) \quad \forall t_k \tag{1}$$

where $\eta_{dc}$ and $\eta_b$ are the efficiency of DC/DC converter and the efficiency of battery bank respectively. Here, we assume that the DC/DC converter is well controlled and the efficiency is known.

The main objective of the power management strategy is to reduce the hydrogen consumption and improve the efficiency of hybrid power system. For a given fuel cell system, the hydrogen consumption along with the output power of fuel cell system is a matter of much concern. So, here, we developed a static fuel cell model. It is assumed that the temperature of the fuel cell system is well maintained at the operating condition (around 65°C) and the pressure difference between the cathode and the anode is ignored. A typical efficiency characteristic of a fuel cell system with a 50-kW rate power is shown in Fig. 2.

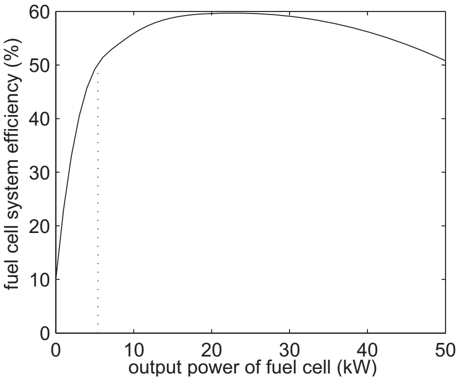

Fig. 2. ADVISOR efficiency map for a 50-kW fuel cell system as a function of output power

The battery pack consists of serially connected battery cells. The internal resistance is the major factor to limit charging and discharging capability. The internal resistance model is used in this study. This model is related to work which was originally performed by Idaho National Engineering Laboratory to model flooded lead-acid batteries [15]. A battery cell is modelled with a voltage source and an internal resistor with temperature ignored (Fig. 3). The resistance and open circuit voltage both are the nonlinear functions of battery state of charge (SOC) (Fig. 4).These relationships are implemented as look-up tables with test data. This simple battery model enables fast calculation for optimization and makes it possible to apply the real time optimization power management strategy.

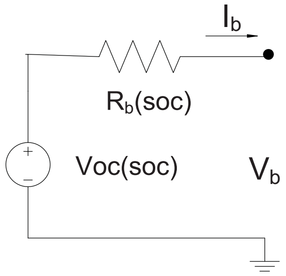

Fig. 3. Internal resistance battery model.

As shown in Fig. 3, the terminal voltage of battery pack $V_b$ can be written by

$$V_b = n_b(V_{oc} - R_b I_b) \tag{2}$$

where $n_b$ is the number of battery cells, $V_{oc}$ is the open circuit voltage of the battery cell, $R_b$ is the internal resistance and $I_b$ is the current flow out the battery. $I_b$ can be calculated by

$$I_b = \frac{V_{oc} - \sqrt{(V_{oc}^2 - \frac{4R_bP_b)}{n_b}}}{2R_b} \tag{3}$$

The SOC of battery is denoted by

$$SOC(k) = SOC_0 - \frac{1}{C_b}\int_{t_0}^{t_k} I_b dt \tag{4}$$

where $k$ is the time step and $C_b$ is the capacity of battery cell.

When the battery pack is discharging, the discharge efficiency of the battery pack can be written as

$$\eta_{dis} = \frac{V_bI_b}{V_{oc}I_b} = \frac{1}{2} + \frac{1}{2}\sqrt{1 - \frac{4R_{dis}P_b}{V_{oc}^2}} \tag{5}$$

where $R_{dis}$ is the discharge resistance of battery cell.

Similarly, for the battery charge process, the charge efficiency is given by

$$\eta_{chg} = \left(\frac{1}{2} + \frac{1}{2}\sqrt{1 - \frac{4R_{chg}P_b}{V_{oc}^2}}\right)^{-1} \tag{6}$$

where $R_{chg}$ is the charge resistance of the battery cell.

## III. Power management strategy of the hybrid power sources

In this section, a power management strategy based on real time optimization is addressed. The main objective of power management strategy is to improve the efficiency of the hybrid system while maintaining the SOC of the battery pack in a certain range.

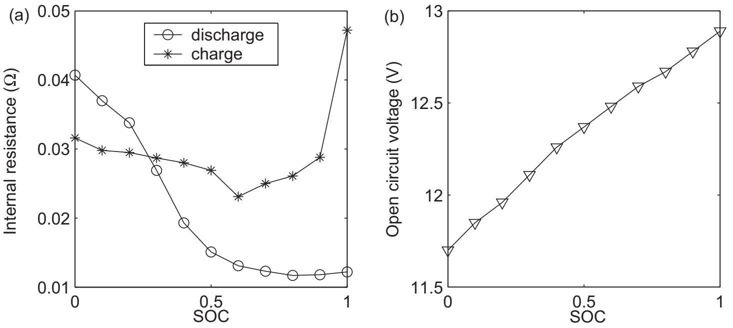

Fig. 4. The relationship between (a)internal resistance and SOC, and (b) open circuit voltage and SOC in ADVISOR.

### *A. The concept of equivalent fuel consumption*

Ideally, The overall efficiency of the hybrid system is defined by

$$\eta_{sys} = \frac{\sum_0^{t_f} P_{load}(t_k)\Delta t_k}{E_{fc} + \sum_0^{t_f} \lambda_{pb}(t_k) P_b(t_k)\Delta t_k} \tag{7}$$

where $\eta_{sys}$ is the overall efficiency of the hybrid system , $P_{load}(t_k)$ is the power supplied in to the vehicle at time step $\Delta t$, $E_{fc}$ is the energy of hydrogen fuel supplied into the fuel cell stack, $P_b(t_k)$ is the battery power of charge or discharge at time step $\Delta t$, $\lambda_{pb}(t_k)$ is the equivalence factor which can be evaluated by the concept of equivalent consumption at time step $\Delta t$.

The energy of hydrogen fuel supplied to the fuel cell during the given mission is calculated according to

$$E_{fc} = \sum_0^{t_f} \frac{P_{fc}(t_k)}{\eta_{fc}(t_k)} \Delta t \tag{8}$$

where $\eta_{fc}(t_k)$ is the efficiency of the fuel cell system at time step $\Delta t_k$ when the output power is $P_{fc}(t_k)$. It can be obtained from the efficiency map of the fuel cell system shown in Fig. 2.

To make the electrical energy consumption of the battery and fuel energy of hydrogen comparable, the electrical energy consumption of the battery is converted into equivalent fuel consumption. Paganelli et al. [16] proposed the concept of equivalent fuel consumption. The concept is that if the battery discharged some power $P_b(t_k)$ at time step $\Delta t$, to maintain the SOC, the battery will be recharged using the energy of the fuel cell in the future. The discharge efficiency can be written as

$$\eta_{dis}(t_k) = \frac{1}{2} + \frac{1}{2}\sqrt{1 - \frac{4R_{dis}(t_k)P_b(t_k)}{V_{oc}(t_k)^2}} \tag{9}$$

where $R_{dis}$ is the discharge resistance of battery.

Similarly, for the battery charge process, the charge efficiency is given by

$$\eta_{chg}(t_k) = \left(\frac{1}{2} + \frac{1}{2}\sqrt{1 - \frac{4R_{chg}(t_k)P_b(t_k)}{V_{oc}(t_k)^2}}\right)^{-1} \tag{10}$$

The battery equivalent fuel consumption is defined as

$$\begin{aligned} &C_b(t_k) = \lambda_{cb}(t_k)\ P_b(t_k) \\ &\lambda_{cb}(t_k) = \begin{cases} \dfrac{C_{fc,avg}}{P_{fc,avg}\eta_{dis}(t_k)\eta_{chg,avg}} & P_b(t_k) \geq 0 \\ \dfrac{C_{fc,avg}\eta_{chg}(t_k)\eta_{dis,avg}}{P_{fc,avg}} & P_b(t_k) < 0 \end{cases} \end{aligned} \tag{11}$$

Because the future operating points are not known, the average charge efficiency of the battery is used and also, the average fuel cell power and its fuel consumption are used.

According to (11), the equivalence factor $\lambda_{pb}(t_k)$ can be calculate by

$$\lambda_{pb}(t_k) = \frac{P_{fc,avg}}{\eta_{fc}C_{fc,avg}}\lambda_{cb}(t_k) \tag{12}$$

### *B. Optimization problem statement*

The problem is to solve this global optimization problem, the load power demand in the given mission has to be known a priori. But in many cases, we can not get this power demand until it is generated by the load, especially in automotive applications. So instead of the global optimization, we reduce the global optimization to a local one. That is, for each time $t_k$ with a time step $\Delta t_k$, we solve the local optimization problem by maximizing the objective $J(t_k)$, defined as

$$J(t_k) = \frac{P_{load}(t_k)\Delta t_k}{(\frac{P_{fc}(t_k)}{\eta_{fc}(t_k)} + \lambda_{pb}(t_k)P_b(t_k))\Delta t_k} \tag{13}$$

The global optimization is not equal to the local problem described above. But it can be easily used for real time control whereas its global counterpart is non-causal and non-realizable [12].

For all $t_k$ the constraints in the fuel cell power and the battery pack power are

$$\begin{array}{ccccc} 0 & \leq & P_{fc}(t_k) & \leq & P_{fc,max} \\ \Delta P_{fc,fallrate} & \leq & \dfrac{\Delta P_{fc}(t_k)}{\Delta t_k} & \leq & \Delta P_{fc,riserate} \\ P_{b,chg,max} & \leq & P_b(t_k) & \leq & P_{b,dischg,max} \\ SOC_{min} & \leq & SOC(t_k) & \leq & SOC_{max} \end{array} \tag{14}$$

where $P_{fc,max}$ is the maximum power that fuel cell system can deliver, $\Delta P_{fc,fallrate}$ and $\Delta P_{fc,riserate}$ are maximum fall rate of $P_{fc}$ and maximum rise rate of $P_{fc}$ respectively. With regard to the battery pack, the maximum power flows are also limited. The maximum power that the battery pack can deliver $P_{b,dischg,max}$ or store $P_{b,chg,max}$ depends on the actual voltage of the battery pack $V_{oc}$, the maximum voltage $V_{b,max}$, and the minimum voltage $V_{b,min}$ [17].

$$P_{b,chg,max} = \frac{n_b V_{oc}(V_{oc} - V_{b,max})}{R_d} \tag{15}$$

$$P_{b,dischg,max} = \frac{n_b V_{oc}(V_{oc} - V_{b,min})}{R_d} \tag{16}$$

Because $V_{oc}$ and $R_d$ both are depend on the SOC of the battery pack, whereas the SOC is various in the duration of the given mission. The values of $P_{b,chg,max}$ and $P_{b,dischg,max}$ are various at each time step in optimization.

To get the optimal power distribution, the local optimization problem that should be solved at each time $t_k$ with a time step $\Delta t_k$ is

$$\begin{array}{lccccc}
 & \underset{P_{fc}}{Maxmize}\, J(t_k) = \frac{P_{load}(t_k)\Delta t_k}{\left(\frac{P_{fc}(t_k)}{\eta_{fc}(t_k)} + \lambda_{pb}(t_k)P_b(t_k)\right)\Delta t_k} \\
s.t. & P_{fc}(t_k)\eta_{dc} + P_b(t_k)\eta_b = P_{load}(t_k) \\
 & 0 & \leq & P_{fc}(t_k) & \leq & P_{fc,max} \\
 & \Delta P_{fc,fallrate} & \leq & \frac{\Delta P_{fc}(t_k)}{\Delta t_k} & \leq & \Delta P_{fc,riserate} \\
 & P_{b,chg,max}(t_k) & \leq & P_b(t_k) & \leq & P_{b,dischg,max}(t_k) \\
 & SOC_{min} & \leq & SOC(t_k) & \leq & SOC_{max}
\end{array} \tag{17}$$

To avoid the "starvation" of reactants in the fuel cell system and take the slow dynamics into account, the output power of fuel cell system is increased no faster than a certain power rise rate $\Delta P_{fc,riserate}$. Also, the power fall rate of the fuel cell system is restricted to prevent overpressure into the stack. $SOC_{max}$ is the upper bound of SOC and $SOC_{min}$ is the lower bound of SOC. As a conservative target, 0.8 and 0.4 are used in this study.

### C. Implementation and practical considerations

The fuel cell system has serval subsystems such as the gas supply subsystem, the humidifying subsystem, the temperature control subsystem and so on. The anode pressure, cathode pressure, the temperature and the moisture should be appropriately controlled. All these control algorithms are achieved through a so-called NetController, which has been developed by CASIA. To reduce the calculation work of NetController, the real time optimization problem is solved in MATLAB, which can also take advantage of MATLAB optimization toolbox. User Datagram Protocol (UDP) communication is adopted to exchange the necessary data between the NetContorller and MATLAB. The proposed real time optimization power management strategy here is shown in Fig. 5.

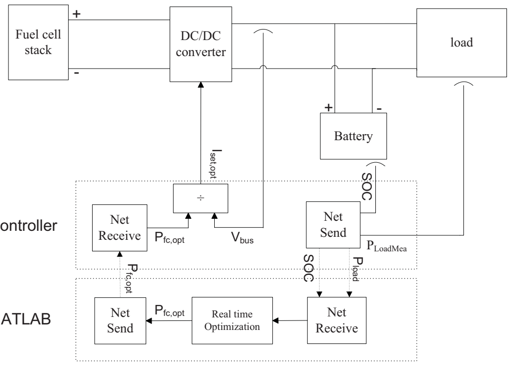

Fig. 5. Proposed power management strategy based on real time optimization

At each time $t_k$ with a time step $\Delta t_k$, the following steps are performed in real time optimization process:

- The load power and the battery SOC are measured by the sensor connected with NetController, and then, these values are sent to MATLAB by UDP communication program.
- MATLAB receives the values of load power and battery SOC, solve the optimization problem shown by 17) and get the optimal set point of fuel cell power $P_{fc,opt}(t_k)$ and the optimal value of $J(t_k)$.
- MATLAB sends the optimal value $P_{fc,opt}(t_k)$ to the NetController.
- The Netcontroller receives the value of $P_{fc,opt}(t_k)$, calculate the set point current of the DC/DC converter.

Get the optimal fuel cell power of the whole cycle

Fig. 6. The simulation flowchart of the proposed power management strategy

## IV. Optimization and experimental results

The proposed power management strategy based real time optimization are tested by simulation and experiments. Section

A is devoted to simulation results and analysis. The implementation of the proposed strategy in an experimental test setup is presented in section B.

## A. Simulation results

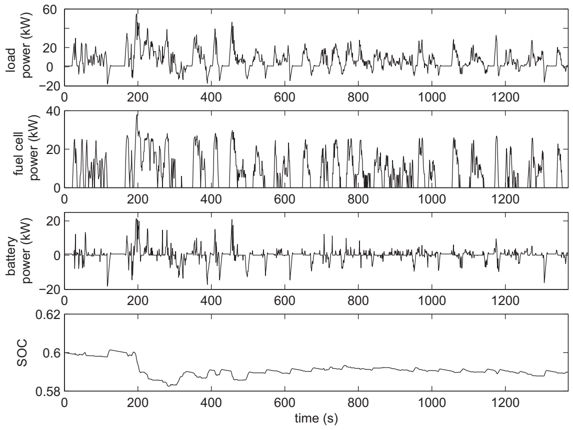

Fig. 7. The simulation results of the proposed strategy for UDDS cycle.

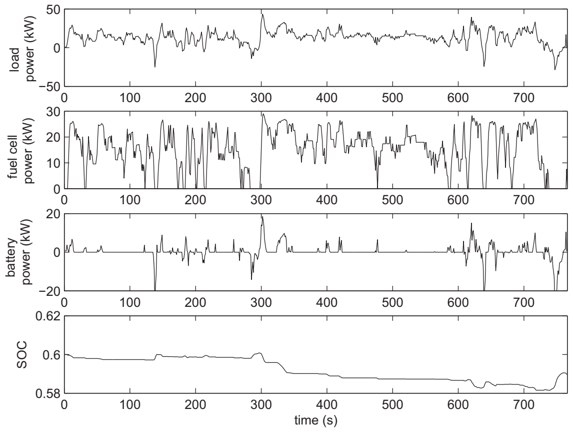

Fig. 8. The simulation results of the proposed strategy for HWFET cycle.

To compare the performance of the proposed real time optimization strategy with other power management strategies especially the global optimization control strategy, we simulated the power demand of a typical vehicle in three driving cycles: UDDS, HWFET, and NEDC. The optimization results of the proposed power management strategy and the optimal fuzzy power management strategy described in literature [14] are shown in Table I. In this table, the degree of hybridization (DOH) is defined as the ratio of electric power can be delivered by the energy storage system (here it means the battery pack) to the total power that can be delivered by ESS and fuel cell system [18]. The simulation is carried out in MATLAB, process of the simulation is shown in Fig. 6.

Fig. 7 shows the simulation results with the real time optimization power management strategy for UDDS cycle. The simulation results for HWFET cycle and NEDC cycle are shown in Fig. 8 and Fig. 9.

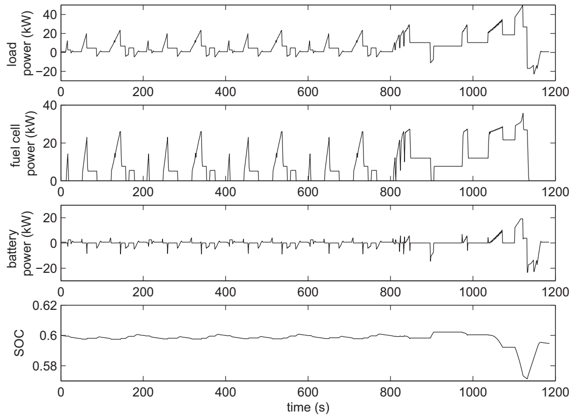

Fig. 9. The simulation results of the proposed strategy for NEDC cycle.

Optimization results in Table I show that the hydrogen economy of the real time optimization power management strategy is not as good as that of the global optimization. That is reasonable because the global optimization strategy is based on power demand of the entire driving cycle which is infeasible in practice, whereas the real time optimization is just based on the present power need.

## B. Experimental validation

In this subsection, the experimental results are presented to validate the feasibility and practicability of the proposed real time optimization power management strategy.

The experimental setup is composed of a PEM fuel cell test rig, a lead-acid battery pack, a constant-voltage restricted-current DC/DC converter and car lights to emulate the power consumption The PEM fuel cell test rig are designed and built by Institute of Automation, Chinese Academy of Sciences(CASIA). 24 cells are connected in series to make up the fuel cell stack. The voltage level can vary from 22V at no load to about 16V at full load. The rated power of this small fuel cell system is 150W and The max rise rate of the fuel cell is 30W/s. The DC/DC converter is connected after the fuel cell system to stable the output voltage and control the fuel cell output power. A 24 AH,12V lead acid is connected to dc bus. Car lights are used as the power load.

The optimization process is executed at every second and the experimental results are shown in Fig. 10. The results show that when the load power demand is the range that the fuel cell and battery can afford, the fuel cell system is apt to work at the power range that the system has the maximum efficiency.

## V. CONCLUSIONS

In this work, a new power management strategy based on real time optimization for fuel cell hybrid power sources system was addressed. Compared to the global optimization strategies that need the power demand of the entire task, which is not feasible in practice, the proposed strategy only

TABLE I

OPTIMIZATION RESULTS COMPARISON OF THE LOCAL OPTIMIZATION STRATEGY AND THE GLOBAL OPTIMIZATION STRATEGY

| Simulation outputs | Units | UDDS cycle | | HWFET cycle | | NEDC cycle | |
|---|---|---|---|---|---|---|---|

need the current power demand and can be easily applied in practice. The proposed strategy was tested both in simulation environment using three standard driving cycles and in an experiment. Compared to other power management strategies, the followings are verified: First, although the hydrogen economy of power management strategy based on real time optimization is not as good as the strategy based on global optimization, the proposed strategy still has a comparative good fuel economy. Second, if the power demand is near constant and the power demand deceleration is low, the fuel economy improved by optimization, no matter local optimization or global optimization, is insignificant. Finally, the experimental test shows that the proposed strategy is very easy to be implemented in practice.

*Abstract*— **One of the main concerns in underground working tunnels is ensuring the safety of the workers and their equipment. Being aware of the real-time position of personnel in such harsh environment is challenging and requires a sophisticated localization system. With traditional Received Signal Strength (RSS) failing to accurately estimate the distance between nodes due to multipath effect in such long and narrow space, Radio Frequency Time-of-Flight (RF-TOF) is proved to be an alternative method for more accurate distance estimation. To reduce the communication cost, a distributed localization scheme is proposed, where a simple Newton Iteration location estimation algorithm is embedded in the blind node. Linear least square estimation is used as the initial value to accelerate the convergence of the iteration. Experimental results show the effectiveness of the proposed scheme.**

## I. INTRODUCTION

With the emergence of various location-based services and other potential application in wireless communication networks, localization in wireless networks has received a great deal of attention in the past decades. Commercial examples range from low-accuracy methods based on cell identification to high-accuracy methods combining wireless network information and satellite positioning [1]. These methods are typically network centric, where the position is determined in the network and presented to the user via a specific service. Applications of such kind of systems are limited where infrastructures or signal coverage are not perfect. Wireless Sensor Networks (WSNs) provide another option to localize targets in their covered area, which is an important complement to the infrastructure based wireless localization systems.

In this paper, a special environment, an underground working tunnel, is focused. Underground working tunnels referred here are railway or road tunnels which are under construction, or coal mines. The common characteristics of such environment are as follows: the space is usually long and narrow, with length of several kilometres and width of several meters, and its structure is changing with construction or production; the power supply and the communication infrastructure are not always available, and there are usually no reliable wired or wireless communication link; the tunnels are underground or in mountain bodies, such that the humidity is high, the air is dirty due to the dust and there are even dangerous gases, such as methane, carbon dioxide, carbon monoxide etc.; the environment is noisy and is full of equipment and workers. These characteristics make the tunnel under construction a dangerous working environment. Accidents often happen causing severe casualty and capital lost. It is urgent to establish an advanced monitoring system, which can obtain the real-time information about the worker and the environment, evaluate the risk level to safeguard the workers.

A distributed localization scheme is proposed in this paper. Using JN5148 wireless module which is embedded with a RF-TOF ranging engine [2], a Newton Iteration based localization algorithm is designed and implemented on the blind node. With no overhead hardware requirement and the distributed characteristics, a cheap but efficient localization system adaptable to constructing tunnel environment can be achieved.

The rest of the paper is organized as follows. In section II, popular localization methods of WSN and the state of the art of tunnel localization are briefly reviewed. Section III presents a Newton Iteration localization algorithm with Linear Least Square Estimation (LLSE) as initial value and a distributed localization scheme is proposed in section IV. Section V demonstrates the experimental results and concluding remarks are made in section VI.

## II. RELATED WORKS

### A. Localization Techniques in WSN

The subject of localization in wireless sensor networks has been drawing considerable attention due to its potential applications, such as inventory tracking, intruder detection, tracking of fire-fighters and miners, home automation and patient monitoring etc. [3, 4]. These potential applications of wireless positioning were also recognized by IEEE, which approved a new amendment, IEEE 802.15.4a, that provides a new physical layer for low data rate communications combined with positioning capabilities [5, 6].

Depending on the mechanisms used, localization schemes in wireless networks can be classified into two categories:

978-1-4673-1560-9/12/$31.00 ©2012 IEEE

range-based and range-free. Range-based approach involves estimation of location in two steps. In the first step, location related parameters, such as Time of Flight (TOF) [7, 8] of signals traveling between the target node (or blind node), i.e. the node to be located, and a number of reference nodes (or anchor nodes) are estimated. Then, in the second step, the location is estimated based on the signal parameters obtained in the first step. The location related parameters estimated in the first step include Received Signal Strength (RSS) [9], Time of Arrival (TOA), Time Difference of Arrival (TDOA) [10, 11], Near Field Electromagnetic Ranging (NFER) [12], which provide an estimation of distance, and Angle Of Arrival (AOA) [13], which estimates the angle between the nodes. For distance based localization algorithms, the maximum likelihood (ML) solution can be obtained by a Nonlinear Least Squares (NLS) approach, under certain conditions [1].

Range-free localization schemes do not need distance or angle information, but performs the localization algorithm based on the connection characteristics and anchor nodes' location information instead. There are some typical algorithms such as centric algorithm [14], DV-HOP algorithm [15], Area-based Point-In-Triangulation Test algorithm (APIT) [16] etc. Range-free localization schemes do not need overhead hardware, so that they are cost-effective and power-effective. But they are usually central schemes and are suitable for simple topology and high densities networks only.

### *B. State of Art of Tunnel Localization*

Range-free localization schemes are not suitable for tunnel environment because of the low density and complex topology of WSN. RSS range-based localization methods have been studied in coal mine galleries [17]. Qiao proposed a dynamic RSS localization algorithm for chain-type WSN in tunnels [18], in which the distance and the corresponding RSS between the adjacent beacon nodes were taken into account to get a better path loss parameter. Impulse Radio Ultra Wideband (IR-UWB) is a promising technology for indoor localization applications due to its high-temporal resolution, multipath immunity, and simultaneous ranging and communication capability. But the receivers need to be connected by cable for high accurate synchronization requirement. Zhou proposed an asynchronous position measurement scheme for indoor localization by adding an additional UWB transmitter besides the anchor nodes and the target nodes [19]. The challenge is that the high accuracy can only be achieved in a smaller coverage. Chehri studied the feasibility of using UWB-based WSN as future solution for localization in underground mine via simulation and measurement [20].

Fingerprinting technique was used in mine localization to avoid the difficulty of measuring distance or angle in such harsh environment [21]. The main disadvantage of such methods is the requirement that the training database should be large enough and representative of the current environment for accurate localization. In underground working tunnels, such data collection task can be laborious or even impossible because of the dynamic change of the structure.

Localization schemes can be categorized into centralized and distributed based on the communications between nodes. Centralized schemes involve transmitting all measured data to a central node to compute the location of the target node and the central node has enough computation resources to carry out complicated localization algorithms. Distributed localization schemes do not require centralized computation, and rely on each node to calculate its location with only limited communications with nearby limited nodes. Distributed scheme is more suitable for tunnel environment where the communication cost to the central node is much higher and the time delay is much bigger because of multi-hop transmission.

### *C. Radio Frequency Time of Flight Ranging*

RF-TOF refers to the time needed for a message to be sent from one node to another. Since the spread velocity of radio is invariable, which is $3\times10^8$ m/s, with RF-TOF obtained, the distance between two nodes can be calculated easily. With the same transceiver used for data communication, an RF-TOF ranging engine requires little hardware overhead and can achieve meter level accuracy in complex environments. RF-TOF ranging occurs in short bursts and in a frequency hopped fashion thereby reducing the chance of interference. RF-TOF ranging is such an attractive option for WSNs that some prototypes have been demonstrated, but work has been largely limited to wide bandwidths and high power devices [22].Optimization of RF-TOF for WSNs has recently received attention with some interesting results in the wideband signal domain [6]. In bandwidth limited systems, measuring the TOF requires accurately resolving the phase offset of a signal. Pseudorandom Noise (PN) codes are good candidate signals for measuring small phase offsets because the autocorrelation function of a PN code exhibits a single large peak that moves with phase offset. Reference [7] proposed a pair-wise ranging called Code Modulus Synchronization (CMS) that does not require either node to determine the absolute phase offset of system clocks, the correlation function or the TOF in real time. This reduces the hardware overhead and measurement time by not requiring a real time co-relator.

Two classes of RF-TOF measurement systems exist. The first is a scheme where a number of significant devices have highly accurate, synchronized clocks. In the simplest case, a signal is sent from a device with a known location and an accurate clock to another device with an accurate clock, and the departure time of the signal is compared to the actual time of arrival. This scheme is not practical in WSNs due to the high accuracy requirement to the hardware. The second type of RF-TOF system is a pair-wise round-trip measurement, which does not require absolute clock. By sending a ranging signal and waiting for a reply, the individual clock biases are subtracted away. Reference [23] proposed a two-way TOF ranging scheme using narrow-band RF chip CC2430.

In this paper, JN5148 microcontroller is utilized as the CPU of wireless sensor nodes, as it embeds an RF-TOF ranging engine [2], which is an alternative of RSS to estimate distance between two nodes without overhead hardware. A chain type of Zigbee network is deployed in underground tunnels, and a distributed Newton Iteration based localization algorithm is designed on the blind node.

## III. Newton Iteration Based Localization Algorithm

### A. Traditional Trilateration Algorithm

In range-based localization scheme, the position of a blind node can be determined with the knowledge of the distance to its neighbouring anchors (i.e. reference nodes) and the coordinates of those anchors:

$$(x-x_i)^2+(y-y_i)^2=d_i^{\,2}, \quad i=1,2,\cdots,N \tag{1}$$

Where $(x, y)$ is the coordinates of the blind node;

$(x_i, y_i)$ is the coordinates of the ith reference node;

$d_i$ is the distance between the blind node and the ith reference node and N is the number of the reference nodes.

In the absence of noise in a system, each distance measurement specifies a circle for the possible positions of the blind node, and the intersection of those circles determines the target position. This geometric technique, called trilateration, yields ambiguous solutions in the presence of noise in the system, since the circles defined by (1) may intersect at multiple points due to erroneous distance estimation. A popular statistical localization algorithm is the Nonlinear Least Squares (NLS) techniques, by which the location of the blind node is calculated as follows:

$$\begin{aligned}[\hat{x},\hat{y}] &= \arg\min_{(x,y)} s(x,y)\\ &= \arg\min_{(x,y)} \sum_{i=1}^{N} \beta_i\left(\sqrt{(x-x_i)^2+(y-y_i)^2}-d_i\right)^2\end{aligned} \tag{2}$$

Where $s(x, y)$ is the cost function, $N \geq 3$ is the number of the reference nodes, and $\beta_i$ represents a weighted coefficient for the ith measurement, which commonly reflects the reliability of the measurement. The solution of (2) usually requires numerical search methods such as the steepest descent or the Gauss-Newton techniques, which can have high computational complexity and typically requires good initial value in order to avoid converging to the local minima of the cost function.

Alternatively, Linear Least Square Estimation (LLSE) can provide suboptimal location estimation with low computational complexity. Let the rth equation represented in (1) subtract all the other equations, (i.e. equation 1, 2, $\cdots$, r-1, r+1, $\cdots$, n), the following linear relation can be obtained:

$$AX=b$$

Where $X=[x, y]^T$ is the location of the blind node,

$$A=2\begin{bmatrix} x_1-x_r & y_1-y_r\\ \vdots & \vdots\\ x_{r-1}-x_r & y_{r-1}-y_r\\ x_{r+1}-x_r & y_{r+1}-y_r\\ \vdots & \vdots\\ x_N-x_r & y_N-y_r \end{bmatrix} \tag{3}$$

$$b=\begin{bmatrix} d_r^2-(x_r^2+y_r^2)-d_1^2+(x_1^2+y_1^2)\\ \vdots\\ d_r^2-(x_r^2+y_r^2)-d_{r-1}^2+(x_{r-1}^2+y_{r-1}^2)\\ d_r^2-(x_r^2+y_r^2)-d_{r+1}^2+(x_{r+1}^2+y_{r+1}^2)\\ \vdots\\ d_r^2-(x_r^2+y_r^2)-d_N^2+(x_N^2+y_N^2) \end{bmatrix} \tag{4}$$

Note that A is an $(N-1)\times 2$ matrix, and b is a $(N-1)$ vector, since the rth measurement is used as a reference for all the other measurement. Then the LLSE can be obtained as

$$\hat{X}=(A^TA)^{-1}A^Tb \tag{5}$$

Reference [24] analysed the performance of several LLSE algorithms, where different information is used as reference. Reference [11] proposed a linear suboptimal location estimation algorithm by constructing a triangle and selecting the best estimation from Seven Potential Estimation (SPE) according to the cost function. With relatively low computational complexity, such algorithms can be implemented in a distributed way.

### B. Newton Iteration with LLSE as Initial Value

To obtain more precise estimation, high-accuracy techniques, such as NLS approach and linearization based on Taylor series can be considered. A good initial value can make the sequence converge quickly and significantly reduce the calculation complexity, thus making it possible to be implemented in a distributed way. In this paper, LLSE solution provided by (5) is utilized as the initial value to accelerate the convergence of Newton iteration, LLSNI for brevity.

Calculate the partial derivatives of $s(x, y)$ in (2) with respect to x and y, denoted as $f(x, y)$ and $g(x, y)$; and let them equal to zero:

$$\begin{cases} f(x,y)=\dfrac{\partial s(x,y)}{\partial x}=\displaystyle\sum_{i=1}^{N}\beta_i\left[2(x-x_i)-\dfrac{2r_i(x-x_i)}{\sqrt{(x-x_i)^2+(y-y_i)^2}}\right]=0\\ g(x,y)=\dfrac{\partial s(x,y)}{\partial y}=\displaystyle\sum_{i=1}^{N}\beta_i\left[2(y-y_i)-\dfrac{2r_i(y-y_i)}{\sqrt{(x-x_i)^2+(y-y_i)^2}}\right]=0 \end{cases} \tag{6}$$

Then the Newton-iteration equation is:

$$\begin{cases} x_{k+1}=x_k+\dfrac{f(x_k,y_k)g_y(x_k,y_k)-g(x_k,y_k)f_y(x_k,y_k)}{g_x(x_k,y_k)f_y(x_k,y_k)-f_x(x_k,y_k)g_y(x_k,y_k)}\\ y_{k+1}=y_k+\dfrac{g(x_k,y_k)f_x(x_k,y_k)-f(x_k,y_k)g_x(x_k,y_k)}{g_x(x_k,y_k)f_y(x_k,y_k)-f_x(x_k,y_k)g_y(x_k,y_k)} \end{cases} \tag{7}$$

Where $f_x(x,y)$, $f_y(x,y)$, $g_x(x,y)$ and $g_y(x,y)$ represent partial derivatives of $f(x,y)$ and $g(x,y)$ with respect to x and y. The detail is omitted for the sake of simplicity. One numerical solution of (6) is

$$\begin{cases} x=\lim\limits_{k\to\infty} x_k\\ y=\lim\limits_{k\to\infty} y_k \end{cases}$$

when the Newton sequence is convergent.

RSS information is included in a RF-TOF ranging package [25]. According to experiment, large RSS value means the distance between two nodes is short and thus the RF-TOF ranging is relatively reliable. Therefore, we choose the measurement with the largest RSS value as the reference in LLSE algorithm, i.e. r in (3) and (4) is defined as:

$$r = \arg\max_{i}(RSS_i)$$

and RSS information is also utilized to calculate the weighting coefficient in the cost function:

$$\beta_i = RSS_i \Big/ \sum_{j=1}^{N} RSS_j \qquad (8)$$

After obtaining all the information needed for localization, including the coordinates of the reference nodes, distance between the blind nodes and each reference node measured by RF-TOF ranging engine, and RSS value when performing RF-TOF, the blind node calculates LLSE according to (5) and uses it as the initial value of Newton Iteration, which is used to calculate the minimum point of the cost function $s(x, y)$ according to (7). Finally, the blind node reports the localization result to the surveillance centre.

## IV. A Distributed Localization System in Underground Tunnels

### A. Architecture of The Localization System

The localization system proposed in this paper consists of a surveillance PC, a coordinator, anchor nodes and one or more blind nodes. The structure of the system is shown in Fig. 1.

The WSN in tunnels is a ZigBee network and the coordinator is responsible for establishing the network. The coordinator also acts as a gateway to the surveillance PC through a serial port. The surveillance PC is responsible for the configuration of the anchor nodes and localization data management.

The anchor nodes collect data of tunnel environment and participate in localization. Anchor nodes are routers of the ZigBee network. The blind node performs a distributed localization algorithm. There can be one or more blind nodes in WSN simultaneously and they must be routers of the ZigBee network, because they need to communicate with multiple anchor nodes directly within their communication range.

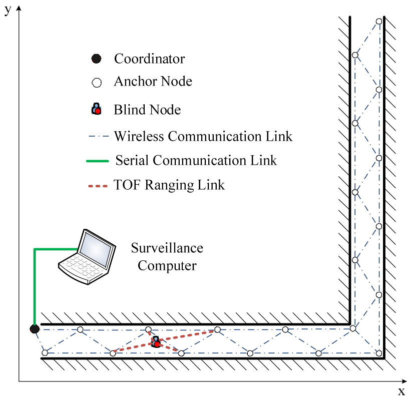

Figure 1. Architecture of the proposed localization system

There is a configurable timer on the blind nodes. When the timer expires, the blind nodes execute the localization task and report the result to the coordinator, and then the timer is restarted again.

### B. Deployment and Configuration of The System

To ensure the network communication having certain redundancy and the blind node finding at least 4 reference nodes, the anchor nodes should be deployed along both sides of the tunnel. The distance between any two adjacent nodes on the same side remains the same, and it should be shorter than their valid communication range. The anchor nodes on different sides should be placed alternately, in other words, one anchor node on one side is to be placed in the middle point of two nodes on the opposite side, as shown in Fig. 3.

There are two parameters that should be configured before the localization system works: the ID number and the coordinates of each anchor node. These parameters should be non-volatile. A unique ID number for each anchor node is defined and configured after the node joins the network. The serial numbers of the anchor nodes on one side are all odd numbers, and are all even numbers on the other side. This rule helps the blind node to choose proper reference nodes on both sides, because if all the reference nodes are on the same side, which means they may be in a line, it will lead to a failure of our localization algorithm.

### C. Distributed Localization Scheme

A distributed localization algorithm is designed and implemented on the blind node, consisting of the following steps:

Step 1) When the blind node enters into the area covered by the ZigBee network, it requests to join the network as a router. After joining the network successfully, the blind node broadcasts a localization request in one hop range, starts a timeout timer and waits for the anchor nodes' response. If the following conditions are satisfied, turn to step2:

Condition 1: There are at least four anchor nodes responding the request with their ID numbers and coordinates, which are the reference nodes for this localization;

Condition 2: Two of the reference nodes have odd ID numbers and the other two have even numbers. It ensures that the reference nodes are not in a line;

If the timeout timer expires before the above conditions are met, the blind node reports the information of not finding enough reference nodes to the coordinator and repeat Step 1.

Step 2) The blind node uses the RF-TOF engine to measure the distance between each reference node and itself. To minimize the measurement errors caused by clock shifts between different nodes, a bidirectional round trip measurement strategy is adopted: the blind node performs M times forward measurement and M times reverse measurement [25]. The average of these 2M results is regarded as the final value. The parameter M can be configured through the surveillance software, and usually within the range of 5~10.

Step 3) The blind node estimates its own coordinates according to the distances between itself and each reference node and the coordinates of the reference nodes, using LLSNI algorithm presented in section III.

Step 4) The blind node reports its coordinates to the coordinator.

When the coordinator receives the localization message, it will hand the message over to the surveillance PC immediately.

## V. Experimental Results

The proposed localization system is tested in an abandoned air-raid shelter. It has an "L" shape, as shown in Fig. 4, with similar environment characteristics to underground tunnels.

### A. *Rang Accuracy Comparison between RF-TOF and RSS*

To show the advantage of RF-TOF ranging method in tunnel environment, a contrast measuring experiment was carried out in a point to point way, using RF-TOF and RSS ranging methods respectively. Both two nodes use the same wireless module, JN5148-001-M03 with a standard power. One is placed at the entry of the air-raid shelter and the other is moving along the air-raid shelter. At each distance, 20 times of TOF ranging and 20 times of RSS ranging were performed. The distance calculation formula is as the following:

$$d = TOF \times 0.0003 \qquad \text{(TOF ranging)}$$

$$d = 0.02 \times 10^{(\frac{108-RSS}{20})} \qquad \text{(RSS ranging)[25]}$$

The average and the standard deviation of the measuring results are shown in Table I. As can be seen from the result, the distance estimation errors according to RSSI increase significantly and the standard deviation of multiple measurements increases with the increase of distance. The energy of the radio signal distorts seriously because of the multi-path fading effect. Therefore, RSSI is not suitable for distance estimation in tunnel environment. On the contrary, TOF ranging shows excellent performance with little standard deviation and the ranging error does not increase significantly with the increase of distance. Most of the ranging errors are less than 3 metres. It proves the choice of our RF-TOF for the study.

### B. *Localization Experiment in Air-raid Shelter*

The structure of an air-raid shelter we used is shown as Fig. 1. The length in X axis and Y axis is 150 meters respectively and the width is 5 meters. The distance between the adjacent anchor nodes on the same side is 30 meters, and the deployment of the two sides is alternate. The ZigBee localization network consists of one coordinator and 21 routers, which are all based on JN5148-M03 wireless modules. One of the routers acts as the blind node, which is needed to be localized in real time. Locations were estimated at 14 test points, with each point being localized 20 times.

TABLE I. The Accuracy Comparison of TOF and RSS Ranging

| **Real distance(m)** | | 10 | 20 | 30 | 40 | 50 | 60 |
|---|---|---|---|---|---|---|---|
| **TOF ranging** | ***Average(m)*** | 11.5 | 19.4 | 29.3 | 41.8 | 48.9 | 58.2 |
| | ***Standard deviation(m)*** | 0.7 | 2.1 | 2.2 | 2.5 | 2.6 | 2.8 |
| **RSS ranging** | ***Average(m)*** | 7.1 | 48.5 | 91.4 | 113.5 | 120.8 | 104.7 |
| | ***Standard deviation(m)*** | 0.4 | 14.1 | 28.9 | 19.6 | 23.9 | 64.8 |

The termination condition of Newton Iteration is

$$\sqrt{(x_{k+1}-x_k)^2+(y_{k+1}-y_k)^2} < 0.001$$

or the iteration has been performed 100 times. Two kinds of initial values were tested: random initial value and LLSE as the initial value. With random initial value, 81% of Newton Iterations converged after 18.5 iterations in average, and 19% reached the maximum iteration boundary. With LLSE as the initial value, 100% of Newton iterations converged after averaged 5.8 iterations in average. The experimental results proved that LLSE initial value accelerated the convergence of Newton Iteration.

Other two existing algorithms, LLSE and SPE, were implemented as well in the same experiment environment.

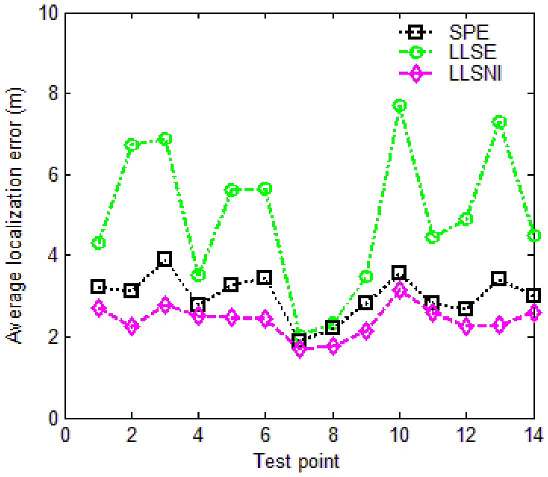

Figure 2. Average localization errors of LLSNI, LLSE and SPE

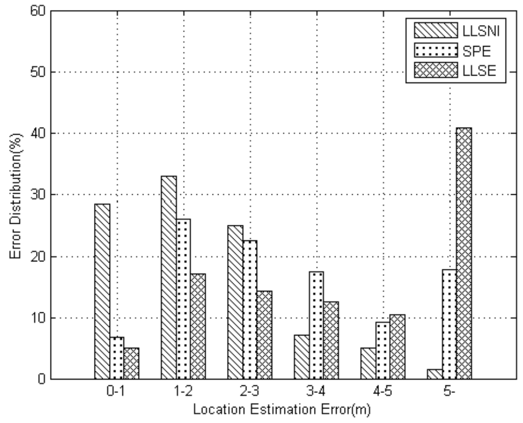

Figure 3. Localization error distribution of LLSE, SPE and LLSNI

These three algorithms were tested under the same condition. Fig. 2 showed the average localization errors of these three algorithms at each test point. Three curves had the similar trend, which means that large range error degraded the performance of all those localization algorithms, but the influence to LLSNI was much smaller than the influence to the other two algorithms. Fig. 3 showed the error distribution of those three algorithms. As can be seen, LLSNI algorithm outperforms theother two algorithms with acceptable computation increase, and 86.4% of the localization errors are less than 3 meters.

## VI. Conclusions

According to the special characteristics of the underground working tunnels, a distributed range-based localization scheme is proposed. RF-TOF range engine embedded in JN5148 microcontroller is utilized to estimate the distances between nodes. A Newton Iteration location estimation algorithm is proposed, with LLSE as the initial value to accelerate the convergence. With low calculation complexity, the localization algorithm can be embedded in the blind node and only the localization result need to be transmitted to the coordinator. This distributed scheme is especially meaningful in multi-hop WSN in underground tunnels, because it can greatly reduce the communication cost and improve the real-time performance.

Experimental results show that the proposed system can provide precise distributed localization without any overhead hardware, which enables the establishment of a cheap but effective constructing tunnel surveillance system to safeguard the workers there.

Several research challenges remain to be addressed. None line of sight propagation is not taken into account in our scheme, which can be a main cause of range error. Some localization results are clearly outlier due to the range error. How to assess and improve the localization performance with geographic information of the tunnels can be considered. Time delay of communication is another issue that should be addressed when the scale of the system becomes bigger.

# Modeling and Simulation of a Coupled Double-Loop-Cooling System for PEM-Fuel Cell Stack Cooling

Martin Schultze, Michael Kirsten, Sven Helmker and Joachim Horn
Institute for Control Engineering
Helmut-Schmidt-University Hamburg
D-22043 Hamburg, Germany

*Abstract*—**PEM (Polymer electrolyte membrane) fuel cell systems are very efficient energy converters. They generate electrical power, low oxygen concentration cathode exhaust gas, water as well as heat. The fuel cell technology has become very attractive for the use on aircraft where it may serve as a replacement for the auxiliary power unit currently being used for generating electrical power. For the use on aircraft coupled double-loop-cooling systems are investigated as different coolants can be used for inner and outer cooling system. As fuel cell electrical power is nonlinearly dependent on stack temperature and current, a cooling temperature control is required.**

**In this study a nonlinear simulation model of a coupled double-loop-cooling system is presented. The effectiveness-NTU method is used to model the intercooler that couples inner and outer cooling loop. This method has the advantage that outlet temperatures are obtained explicitly based on inlet coolant temperatures and cooling mass flows. The model is valid over the entire operating range of the hydrogen fed fuel cell system. Subsequently, a linear controller with feedforward control is proposed to control for the stack inlet cooling temperature.**

***PEM fuel cell system model; nonlinear heat exchanger model; model identification; fuel cell temperature control***

## I. Introduction

For aircraft applications the fuel cell technology is investigated regarding to its multifunctional use. One of its main aspects is the use of oxygen depleted cathode exhaust air (ODA) for tank inerting [1]. For this purpose the oxygen content needs to be close or less than 10% (vol.) [2]. Another and certainly one of the most important aspects of the multifunctional use is electrical power generation. So far, auxiliary power units (APU) generate electrical power for the use on aircraft during ground operations. An APU, though, is a significant source of green house gases such as $CO_2$ and $NO_x$ and noise. Therefore, hydrogen-gas fed PEM fuel cell systems are studied as a replacement for APUs to significantly reduce these pollutants. Among the different types of fuel cells, PEM fuel cells are the most suitable ones for dynamic applications. Nonetheless, proper fuel cell system operation such as a well humidified membrane or a proper supply of reactant gases and well kept gas pressure is central for a maximum fuel cell lifetime [3]. In this study a fuel cell system with anode hydrogen recirculation for stack humidification is used. Proper fuel and air supply as well as the temperature difference across the stack is managed by an internal fuel cell system controller. The fuel cell system is connected to a controllable ohmic load that draws a current as requested. A schematic of the fuel cell system and its coupled two-loop-cooling system is shown in figure 1.

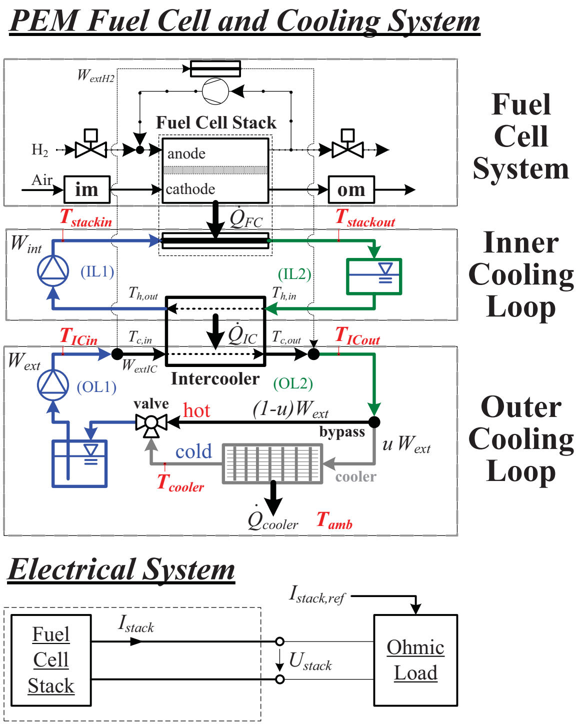

Figure 1. Schematic of the fuel cell system and the connected double-loop cooling system; the fuel cell system comprises the fuel cell stack, inlet and outlet manifolds and anode hydrogen recirculation; the cooling system comprises the inner and outer loop that are interconnected by a counter-flow heat exchanger, connecting pipes, a cooling valve and a cooler; heat flows from stack into the inner loop, inside the intercooler and in the cooler are shown (top); the fuel cell system is connected to an ohmic load (bottom)

The fuel cell system simulation model is based on models reported of in [4], [5] and [6]. Furthermore, product water leaves the fuel cell cathode as vapor and liquid. This has an influence on stack temperature and is taken into account as presented in [7] and [8]. The fuel cell system model is briefly outlined in section Simulation Model. The cooling system is modeled based on first principles. Heat exchanger models as

This study as part of the project "cabin technology and multifunctional fuel cell systems" has been supported by Airbus and the German Federal Ministry of Education and Research (support code: 03CL03A).

proposed in [9] and [6] are restricted on operating range. The effectiveness-NTU method [10] provides nonlinear models for several designs of heat exchangers. Ref. [11] uses this approach for a single-loop cooling system of an automotive fuel cell system assuming constant heat exchanger effectiveness. Constant effectiveness, however, might not hold true for the entire operating range. Here, the effectiveness-NTU method with mass flow dependent effectiveness is used to develop an intercooler model for the coupled double-loop-cooling system. The fuel cell system and intercooler model have been fit to experimental data, which is presented in section Model Identification. Actuating the cooling valve in the outer loop influences the stack inlet temperature in the inner cooling loop. To operate the fuel cell system at a certain stack inlet temperature a temperature controller with feedforward control is proposed in section Controller Design. A simulation of the nonlinear fuel cell and cooling system model with temperature controller are presented in section Simulation results.

## II. SIMULATION MODEL

The overall system simulation model consists of a model of the fuel cell system, a model of its internal fuel cell system controller and a model of the controllable ohmic electrical load to which the fuel cell system is connected. A list of the model parameters is given in table 1 at the end of this paper. Inlet air is taken from an air pressure tank that is filled by a compressor. After compression air is cooled, dried and oil-filtered.

### A. Fuel Cell System Model

The fuel cell system model comprises the fuel cell stack, a mass flow controller (MFC) for cathode air supply and the anode hydrogen recirculation for better hydrogen utilization and stack humidification. The internal fuel cell system controller operates the mass flow controller such that it delivers an air mass flow as specified by stoichiometry and stack current drawn. Furthermore, the internal controller operates the cooling pump in the inner cooling loop to set the reference temperature difference across the fuel cell stack. Inlet air is modeled as a dry and ideal gas consisting of 21% (vol.) oxygen and 79% (vol.) nitrogen. It has constant temperature.

#### 1) Inlet Manifold Model

Inlet manifold pressure $p_{im}$ (1) is gained by a pressure differential equation ($\gamma=1.4$ [5]). In- and outlet temperature are assumed to be equal and constant. Flow $W_{im}$ of dry air exiting the manifold is modeled by a linear nozzle equation (2) with nozzle constant $k_{im}$ and the pressure difference of manifold and cathode pressure $p_{ca}$. Mass flow of dry air $W_{MFC}$ (3) entering the manifold is supplied by a mass flow controller, which is modeled as a first order transfer function with time constant $T_{MFC}$. The mass flow reference is calculated using the reference stoichiometry $\lambda_{ref}$ and the stack current $I_{stack}$ being drawn.

$$\frac{dp_{im}}{dt} = \frac{\gamma R_{air}}{V_{im}} T_{im}\left(W_{MFC} - W_{im}\right) \tag{1}$$

$$W_{im} = k_{im}\left(p_{im} - p_{ca}\right) \tag{2}$$

$$W_{MFC} = \frac{1}{T_{MFC}s+1}\left[I_{stack}\lambda_{ref}\left(M_{O2} + \frac{0.79}{0.21}M_{N2}\right)\frac{n_{cells}}{4F}\right] \tag{3}$$

#### 2) Outlet Manifold Model

Vapor mass flow is obtained by water loading (4) of the dry gas mass flow. Water loading depends on total gas pressure $p_i$ and vapor partial pressure $p_{i,v}$ (5), which solely depends on temperature [12]. Mass flows of water vapor $W_{ca,v}$, oxygen depleted air $W_{ca,oda}$ and liquid water $W_{ca,l}$ are supplied to the outlet manifold at stack temperature $T_{stack}$. The manifold is considered perfectly insulated. Mass flows $W_{om,v}$, $W_{om,oda}$ and $W_{om,l}$ exit directly to the ambient environment and are governed by a linear nozzle equation with constant $k_{om}$ and manifold and ambient pressure difference (6). The flow of liquid water leaving the manifold (7) is modeled to be dependent on the gas mass flow, the liquid water mass $m_{om,l}$ and a constant $\delta_l$ [7].

$$X_i = \frac{p_{v,i}}{p_i - p_{v,i}}\frac{R_{air}}{R_v} \tag{4}$$

$$p_v^{sat} = \exp\left(17.2799 - \frac{4102.99}{\vartheta + 237.431}\right)0.611657\times10^3 \tag{5}$$

$$W_{om} = k_{om}\left(p_{om} - p_{amb}\right) \tag{6}$$

$$W_{om,l} = \delta_l W_{om} m_{om,l} \tag{7}$$

Partial pressures of dry gas $p_{om,oda}$ and vapor $p_{om,v}$ are gained by a mass balance and the ideal gas law (8) with manifold volume $V_{om}$ and the vapor gas constant $R_v$. ODA is approximated as air with gas constant $R_{oda}$=$R_{air}$. Condensation is considered happening instantaneously leading to the condensate mass $m_{om,l}$. The outlet manifold pressure is the sum of oda and vapor partial pressures $p_{om} = p_{om,oda} + p_{om,v}$.

$$\frac{dm_{om,oda}}{dt} = W_{ca,oda} - W_{om,oda}\,, \qquad W_{om,oda} = \frac{1}{1+X_{om}}W_{om}$$

$$\frac{dm_{om,H2O}}{dt} = W_{ca,v} + W_{ca,l} - W_{om,v} - W_{om,l}\,, \quad W_{om,v} = \frac{X_{om}}{1+X_{om}}W_{om}$$

$$p_{om,oda} = \frac{T_{om}R_{oda}}{V_{om}}m_{om,oda} \tag{8}$$

$$p_{om,v} = \min\left(p_v^{sat}(T_{om}), m_{om,H2O}\frac{R_vT_{om}}{V_{om}}\right) \tag{9}$$

$$m_{om,l} = \max\left(0, m_{om,H2O} - p_v^{sat}(T_{om})\frac{V_{om}}{R_vT_{om}}\right) \tag{10}$$

#### 3) Fuel Cell Stack Electrical Model

The stack voltage $U_{stack} = n_{cells}\,U_{cell}$ is the sum of all $n_{cells}$ cell voltages. The cell voltage is modeled as $U_{cell} = U_{rev} - \eta_{act} - \eta_{\Omega}$ (11) with the reversible cell voltage $U_{rev}$, activation loss $\eta_{act}$ [13] and ohmic loss $\eta_{\Omega}$ [14]. The membrane thickness is given by $d_m$ and the active surface area by $A_{sfc}$. Parameters $\zeta_1,\ldots\zeta_4$ and $b_1,\ldots b_3$ have been identified using experimental data.

$$\begin{aligned} U_{rev} &= 1.229 - 0.85\cdot10^{-3}\left(T_{stack} - 298.15\right) + 4.3\cdot10^{-5}T_{stack}\left(\ln\tfrac{p_{H2}}{p_0} + \tfrac{1}{2}\ln\tfrac{p_{O2}}{p_0}\right) \\ \eta_{act} &= \zeta_1 + \zeta_2T_{stack} + \zeta_3T_{stack}\ln\left(p_{O2}e^{\left(498/T_{stack}\right)}/5.08\cdot10^{-6}\right) + \zeta_4T_{stack}\ln\left(I_{stack}\right) \\ \eta_{\Omega} &= \frac{d_m}{\left(b_1\lambda_m - b_2\right)}e^{-b_3\left(\frac{1}{303}-\frac{1}{T_{stack}}\right)}\frac{I_{stack}}{A_{sfc}} \end{aligned} \tag{11}$$

#### 4) Fuel Cell Stack Thermal Model

An energy balance (12) leads to the fuel cell stack temperature $T_{stack}$. The stack has a heat capacity of $C_{st}$. The heat generated through the chemical reaction is given by the chemical energy of hydrogen (HHV) and stack electrical energy. The stack is cooled by convective cooling with coolant mass flow $W_{cool} = W_{int}$ and specific heat capacity $c_{cool}$. The coolant stack inflow temperature is $T_{stackin}$. The coolant leaves the stack at stack temperature. Air, cathode water, vapor and oda gas are assumed to leave the stack at stack temperature as well. Air enters the stack at temperature $T_{im}$. Oda gas is approximated as air with specific heat capacity $c_{oda}= c_{air}$. The stack is very well insulated. So, heat transfer to surroundings is neglected. Enthalpy of evaporation is $h_0$.

$$\begin{aligned} C_{st}\frac{dT_{st}}{dt} &= \left(1.48\,n_{cells} - U_{stack}\right)I_{stack} \\ &+ W_{cool}c_{cool}\left(T_{stackin} - T_{stack}\right) \\ &+ W_{im}c_{air}\left(T_{im} - T_0\right) - W_{oda}c_{oda}\left(T_{stack} - T_0\right) \\ &- W_{ca,l}c_l\left(T_{stack} - T_0\right) - W_{ca,v}\left(h_0 + c_v\left(T_{stack} - T_0\right)\right) \end{aligned} \tag{12}$$

### 5) Fuel Cell Stack Anode and Cathode Model

Anode pressure $p_{an} = p_{H2} + p_{an,v}$ is the sum of hydrogen and vapor partial pressures and is governed by mass conservation (13) and the ideal gas law with $R_{H2}$ being the hydrogen gas constant. In operation a mass flow $W_{H2rct} = (M_{H2}\, I_{stack}\, n_{cells})/(2F)$ of hydrogen is consumed. The stack is operated dead-ended and the system behavior is mimicked by a proportional controller for anode pressure $p_{an}$ with hydrogen inlet mass flow $W_{H2in}$, anode reference pressure $p_{an\_ref}$ and controller gain $k_{an}$ (14). Condensation is modeled happening instantaneously [5] if the vapor pressure exceeds saturation vapor pressure. The mass of condensate and the vapor partial pressure are modeled according to (9) and (10) with water mass (13). The anode water activity $a_{an}$ is modeled as $a_{an}= p_{an,v}/p_v^{sat}$.

$$\frac{dm_{an,H2O}}{dt} = -W_{mem} \text{ and } \frac{dp_{H2}}{dt} = \frac{T_{stack}R_{H2}}{V_{an}}\left(W_{H2in} - W_{H2rct}\right) \tag{13}$$

$$W_{H2in} = k_{an}\left(p_{an\_ref} - p_{an}\right) \tag{14}$$

The cathode inlet mass flows of oxygen and nitrogen are governed by the mass fractions $x_{O2}$ and $x_{N2}$ assuming dry inlet air consisting of 21% of oxygen and 79% of nitrogen. The cathode exit mass flow $W_{ca}$ is modeled as a 3-phase-flow (15) and is governed by a linear nozzle equation similar to (2) with constant $k_{ca}$ and pressure difference ($p_{ca}$ - $p_{om}$). Liquid water mass flow $W_{ca,l}$ is modeled according to (7). Cathode pressure $p_{ca} = p_{O2} + p_{N2} + p_{ca,v}$ is the sum of oxygen, nitrogen and vapor partial pressures and is governed by mass conservation (16) and the ideal gas law [5]. In operation a mass flow $W_{O2rct} = (M_{O2}\, I_{stack}\, n_{cells})/(4F)$ of oxygen is consumed and $W_{H2Orct} = (M_{H2O}\, I_{stack}\, n_{cells})/(2F)$ of water is generated. Condensation happens instantaneously. The vapor partial pressure and liquid mass in the cathode is modeled according to (9) and (10) using the water mass $m_{ca,H2O}$ in (16).

$$\begin{bmatrix} W_{im,O2} \\ W_{im,N2} \end{bmatrix} = \begin{bmatrix} x_{O2} \\ x_{N2} \end{bmatrix} W_{im} \text{ and } \begin{bmatrix} W_{ca,O2} \\ W_{ca,N2} \\ W_{ca,v} \end{bmatrix} = \frac{1}{1+X_{CA}} \begin{bmatrix} \frac{m_{O2}}{m_{O2}+m_{N2}} \\ \frac{m_{N2}}{m_{O2}+m_{N2}} \\ X_{CA} \end{bmatrix} W_{ca} \tag{15}$$

$$\begin{aligned} \frac{dm_{ca,H2O}}{dt} &= W_{mem} + W_{H2Orct} - W_{ca,v} - W_{ca,l} \\ \frac{dm_{O2}}{dt} &= W_{im,O2} - W_{O2rct} - W_{ca,O2} \\ \frac{dm_{N2}}{dt} &= W_{im,N2} - W_{ca,N2} \end{aligned} \quad , \quad \begin{aligned} p_{O2} &= m_{O2}\frac{T_{stack}R_{O2}}{V_{ca}} \\ p_{N2} &= m_{N2}\frac{T_{stack}R_{N2}}{V_{ca}} \end{aligned} \tag{16}$$

### 6) Fuel Cell Stack Membrane Model

Membrane material is Nafion®. The membrane water mass flow $W_{mem}$ (17) is caused by gradient driven diffusion and electro-osmotic drag of water from anode to cathode [14]. Diffusion constant $D_{diff}$ depends on the membrane hydration $\lambda_{mem}$ and stack temperature (18). The membrane water activity $a_{mem}$ is modeled as the average between cathode and anode water activity [14] (with j=*mem, ca, an*).

$$W_{mem} = A_{sfc}M_w n_{cells}\left(\lambda_{mem}\frac{2.5}{22}\frac{I_{stack}}{A_{sfc}F} - \frac{\rho_{dry}}{M_{dry}}D_{diff}\frac{\lambda_{ca}-\lambda_{an}}{d_m}\right) \tag{17}$$

$$D_{diff} = e^{2416\left(1/303-1/T_{st}\right)}\left(2.563-0.33\lambda_{mem}+0.0264\lambda_{mem}^2-0.000671\lambda_{mem}^3\right)\cdot 10^{-6}$$

$$\lambda_j = \begin{cases} 0.043 + 17.81a_j - 39.85a_j^2 + 36.0a_j^3 & 0 < a \le 1 \\ 14 + 1.4\left(a_j - 1\right) & 1 < a \le 3 \end{cases} \tag{18}$$

### 7) Electrical Load Model

The stack is connected to a controllable ohmic load drawing a current as requested by a reference. An internal controller quickly adjusts the load resistance. To prevent numerical problems, the load is modeled as a first order transfer function with time constant $T_L$.

## B. Cooling System Model

As shown in figure 1 the cooling system consists of an inner and an outer cooling loop that are interconnected by an counter-flow heat exchanger also called intercooler. In the inner loop pipes connect the intercooler and the stack.

### 1) Inner Cooling Loop Model

The cooling pump in the internal cooling circuit is controlled such that the cooling temperature difference across the stack equals the reference signal given by the stack manufacturer. The pump generates a coolant mass flow $W_{int}$, which is limited to a minimum of $W_{int,min}$ and a maximum of $W_{int,max}$. The cooling pump controller is modeled as a proportional and integral controller with anti-windup to prevent integrator windup. The pipes are modeled according to [13] and are considered perfectly insulated (20) with specific heat capacity $c_{int}$ and $m_{pipe,i}$ being the mass of coolant in pipe *i*, the coolant inlet temperature $T_{pipein,i}$ and the pipe outlet temperature $T_{pipe,i}$. Using notation of figure 1 the temperature of pipe IL1 is $T_{stackin}$ and of pipe IL2 is $T_{stackout}$. The indices for the model equations (20) are *i*=IL1, IL2.

$$m_{pipe,i}c_{int}\frac{dT_{pipe,i}}{dt} = W_{int}c_{int}\left(T_{pipein,i} - T_{pipe,i}\right) \tag{20}$$

### 2) Outer Cooling Loop Model

The outer loop consists of an air-cooled heat exchanger (cooler) that cools the coolant to a temperature of $T_{cooler}$ and pipes that connect the cooler with the intercooler. In a cooling valve warm coolant from the intercooler and cold cooling fluid from the cooler can be mixed. Warm coolant bypasses the cooler such that is does not cool down. As the bypass pipe is very short as compared to the other pipes its dynamics are neglected. The cooler is modeled as a pipe as well (21). The heat transferred to the surroundings is modeled by the coefficient $k_{cooler}$ and the difference of cooler to ambient temperature $T_{amb}$. The mass flow in the external cooling loop is $W_{ext}$ and the specific heat capacity of the coolant is $c_{ext}$. Using notation of figure 1 the temperature of pipe OL1 is $T_{ICin}$ and of pipe OL2 is $T_{ICout}$. The indices for the model equations (21) are $i$=OL1, OL2.

$$m_{pipe,i}c_{ext}\frac{dT_{pipe,i}}{dt}=W_{ext}c_{ext}\left(T_{pipein,i}-T_{pipe,i}\right)$$
$$m_{cooler}c_{ext}\frac{dT_{cooler}}{dt}=u_{valve}W_{ext}c_{ext}\left(T_{ICout}-T_{cooler}\right)-k_{cooler}\left(T_{cooler}-T_{amb}\right) \qquad (21)$$

In pipe OL2 the coolant for the hydrogen recirculation pump mixes with the coolant of the intercooler outflow. This temperature mixture is modeled by a stationary energy balance (22) with thermal input of the hydrogen pump and assuming that the mass flow through the recirculation pump $W_{extH2}$ is 6% of $W_{ext}$. $T_{c,out}$ is the intercooler outlet temperature. The mass flow through the intercooler $W_{extIC}$ is taken as 94% of the mass flow in the external cooling loop.

$$W_{ext}T_{ICout}=W_{extH2}\left(T_{ICin}+\frac{\dot{Q}_{H2pump}}{W_{extH2}c_{ext}}\right)+W_{extIC}T_{c,out} \qquad (22)$$

### 3) Cooling Valve Model

The mixing temperature of the cooling valve is modeled by a stationary energy equation (23) as the mixing process is considered very fast. The valve splits the mass flow through cooler and bypass given by its actual position $u_{valve}$.

$$W_{ext}T_{pipein,OL1}=u_{valve}W_{ext}T_{cooler}+\left(1-u_{valve}\right)W_{ext}T_{ICout} \qquad (23)$$

The cooling valve has limited dynamics. This results in a limited speed of opening and closing the valve. For small changes in position it behaves linearly. It is modeled having a constant opening and closing speed $du_{max}$ for large changes and behaves like a first order transfer function for small changes in valve position (24). Reference position is $u_{valve,ref}$.

$$\frac{du_{valve}}{dt}=\int k_{valve}\left(u_{valve,ref}-u_{valve}\right)\begin{array}{cc} du_{max} & k_{valve}\left(u_{valve,ref}-u_{valve}\right)>du_{max} \\ & otherwise \\ -du_{max} & k_{valve}\left(u_{valve,ref}-u_{valve}\right)<-du_{max}\end{array} \qquad (24)$$

### 4) Intercooler Model

The counter-flow heat exchanger that connects the inner and outer cooling loop is considered static. This assumption is motivated by the high mass flows in the cooling system and the small coolant mass inside the intercooler as compared to the entire cooling system. For modeling counter-flow heat exchangers the effectiveness NTU method [10] has shown very good results. NTU is the number of transfer units, which is an important parameter in heat exchanger design and modeling. The effectiveness NTU is advantageous as outlet temperatures are calculated explicitly on inlet temperatures and cooling mass flows. Heat flow is gained by the inlet temperature differences, the minimum heat capacity flow and the effectiveness $\varepsilon$. The outlet temperatures (25) are gained by the heat capacity flow of the hot side $C_h$=$W_{int}c_{int}$ and the cold side $C_c$=$W_{extIC}c_{ext}$. The outlet temperatures are $T_{c,out}$ and $T_{h,out}$ for cold and hot side. The inlet temperatures are $T_{c,in}$=$T_{ICin}$ and $T_{h,in}$=$T_{stackout}$.

$$T_{c,out}=T_{c,in}+\frac{\varepsilon C_{min}}{C_c}\left(T_{h,in}-T_{c,in}\right)$$
$$T_{h,out}=T_{h,in}-\frac{\varepsilon C_{min}}{C_h}\left(T_{h,in}-T_{c,in}\right) \qquad (25)$$

$$C_{min}=\min\left(C_h,C_c\right),\ C_{max}=\max\left(C_h,C_c\right),\ C^*=\frac{C_{min}}{C_{max}},\ NTU=\frac{UA}{C_{min}}$$

The heat exchanger effectiveness $\varepsilon$ is obtained by (26). $UA$ is the parameter describing the heat transfer.

$$\varepsilon=\begin{cases}\dfrac{NTU}{1+NTU} & C^*=1 \\ \dfrac{1-\exp\left(-NTU\left(1-C^*\right)\right)}{1-C^*\exp\left(-NTU\left(1-C^*\right)\right)} & otherwise\end{cases} \qquad (26)$$

## III. Model Identification

As shown in the previous paragraphs, the fuel cell system model as well as the cooling system model has parameters describing the plant geometry such as manifold volumes and coolant masses and parameters for mass flows, polarization curve and the intercooler. Parameters $\zeta_1,\ldots\zeta_4$ and $b_1,\ldots b_3$ for the polarization curve, $k_{im}$, $k_{ca}$, $k_{om}$ and $k_{an}$ for the mass flows have been identified by a least square error minimization such that simulated inlet and outlet manifold as well as cathode and anode pressure and simulated stack voltage fit to experimental data. Cathode pressure cannot be measured, therefore, it is assumed as the arithmetic mean of the inlet and outlet manifold pressures. The objective function (27) has scaling factors for pressure $\mu_p$ and voltage $\mu_U$ such that quadratic errors of the same order are gained.

$$\begin{aligned}J_{FCS,i}=&\mu_p\left(p_{im,\exp,i}-p_{im,sim,i}\right)^2+\mu_p\left(p_{ca,\exp,i}-p_{ca,sim,i}\right)^2\\&+\mu_p\left(p_{om,\exp,i}-p_{om,sim,i}\right)^2+\mu_p\left(p_{an,\exp,i}-p_{an,sim,i}\right)^2\\&+\mu_U\left(U_{stack,\exp,i}-U_{stack,sim,i}\right)^2\\J_{FCS}=&\sum_i J_{FCS,i}\end{aligned} \qquad (27)$$

Simulation results of the stationary fuel cell system model after identification of the polarization curve for different sets of stoichiometry and stack inlet cooling temperature are shown in figure 2. The results for inlet as well as outlet manifold and anode pressure are shown in figure 3. As the comparison between experimental data and simulation model shows, the model fits the experimental data very well.

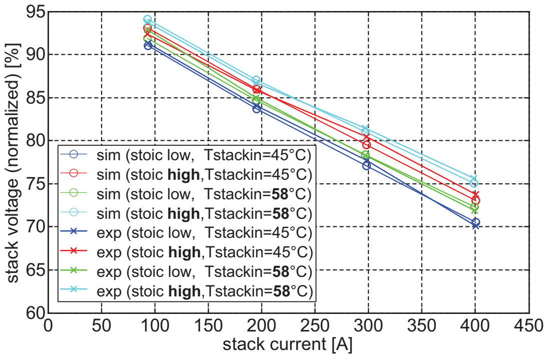

Figure 2. Comparison of experimental and simulation model fuel cell stack polarization curves for different sets of stack inlet temperature (45 and 58°C) and cathode stoichiometry (high and low stoic)

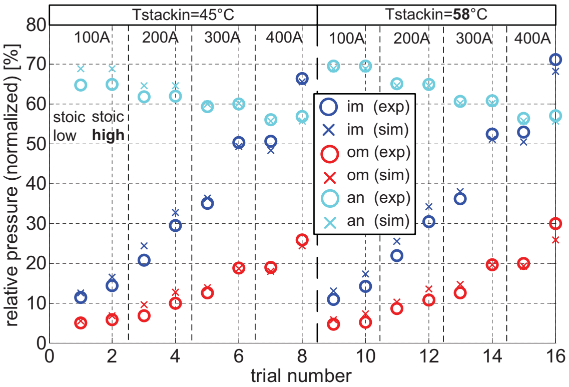

Figure 3. Comparison of experimental and simulation inlet manifold (im), outlet manifold (om) and anode (an) pressures; 16 sets of combinations of stack current, stack inlet temperature and cathode stoichiometry (stoic)

To capture the slow temperature dynamics in the simulation model as well, the stack heat capacity was determined by comparing stack temperature of simulation and experiment until results agreed well. For determining the stack heat capacity cooling mass flow and inlet temperature as well as stack current were prescribed. Simulation results with a PI-controlled cooling pump and stack current, stoichiometry and the coolant inlet temperature prescribed are shown in figure 4 and 5. The dynamic simulation results show that deviations between model and experiment in terms of pressure as well as stack voltage are small. The dynamic simulation model fits the experimental data very well.

### 1) *Identification of the Intercooler Model*

Parameter *UA* of the intercooler model has been identified by a least square error minimization as well. For model identification it was assumed that temperature measurement errors compensate as the temperature difference across the heat exchanger is taken. The cooling mass flow $W_{int,measure}$ of the internal cooling loop can be considered an exact measurement. The cooling mass flow in the external cooling loop $W_{ext,measure}$, however, is corrected by a constant factor $\alpha$ to minimize the difference between the stationary energy balances of hot and cold side (28). The stationary balance is determined by cooling mass flow, specific heat capacity of the coolant and the temperature difference.

$$J_Q = \sum_i \dot{Q}_{h,i} - \dot{Q}_{c,i} \\ = \sum_i W_{\text{int},measure,i} c_{\text{int}} \Delta T_{\text{int},measure,i} - \alpha W_{ext,measure,i} c_{ext} \Delta T_{ext,measure,i} \tag{28}$$

Heat flows resulting from an energy balance about inner and outer cooling loop are shown in figure 6. Using $W_{int,measure}$, the corrected mass flow $\alpha W_{ext,measure}$ and temperatures of hot and cold fluid at in- and outlet the intercooler parameter *UA* has been identified by a least square error minimization with objective function (29). Coolant mass flows and temperatures at the heat exchanger inflow at inner and outer loop were prescribed. *UA* has been fit to minimize the difference between simulated and measured coolant temperatures at the intercooler outflows.

$$J_T = \sum_i \left(T_{hout,\exp,i} - T_{hout,sim,i}\right)^2 + \left(T_{cout,\exp,i} - T_{cout,sim,i}\right)^2 \tag{29}$$

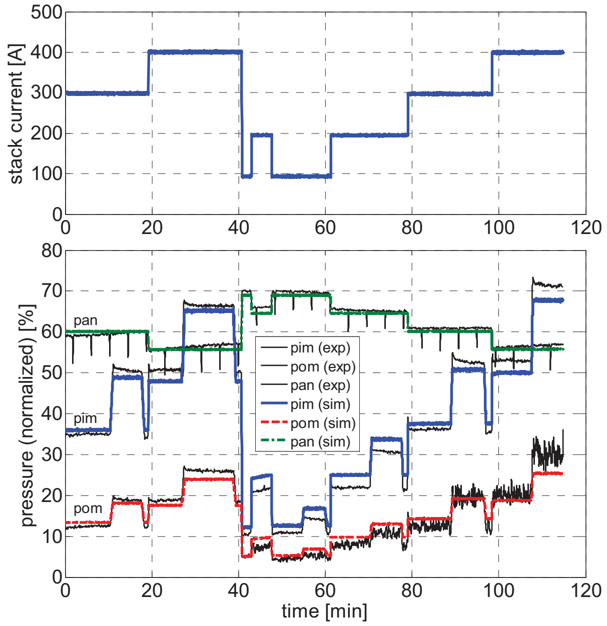

Figure 4. Simulation results dynamic fuel cell system model: experimental stack current profile also used as current profile for the simulation model (top); in- and outlet manifold and anode pressure of simulation and experiment (bottom)

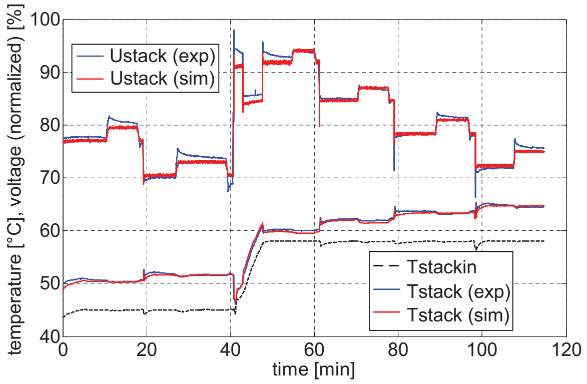

Figure 5. Simulation results fuel cell system model: stack cooling and stack temperature and stack voltage of simulation and experiment

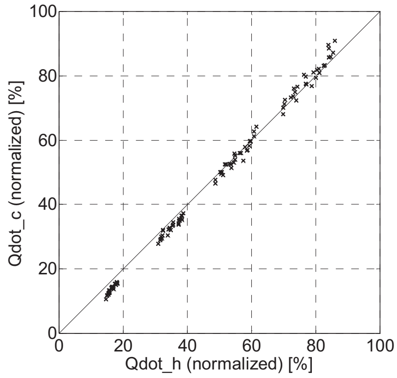

Figure 6. Stationary heat flows leaving the inner cooling loop (Qdot_h) and being brought into the outer cooling loop (Qdot_c) at the intercooler with corrected cooling mass flow of the outer cooling loop

A comparison of simulation results and experimental data for different sets of stack current, outer loop cooling temperature and cooling mass flow are shown in figure 5. An increase of stack current leads to an increase of coolant temperature in the inner loop as the thermal load is increased which can be seen by the polarization curve in figure 2.

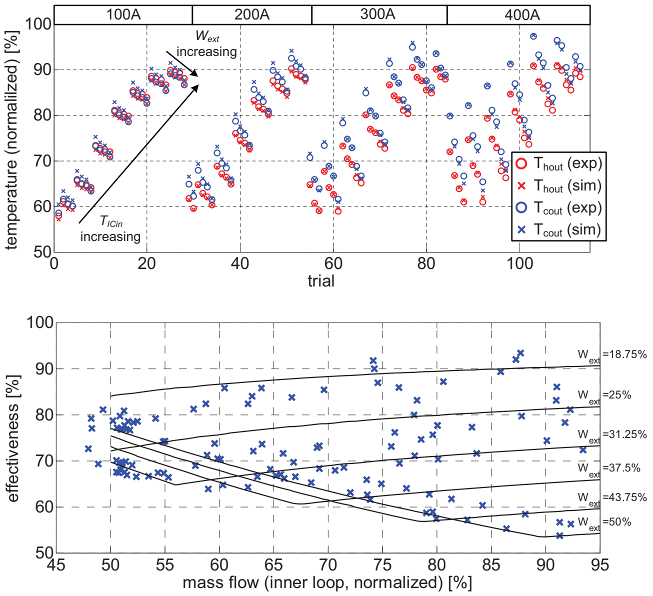

Figure 7. Comparison of experimental and simulation model outlet temperature of inner ($T_{hout}$) and outer ($T_{cout}$) cooling loop; for different sets of stack current, outer loop cooling temperature $T_{ICin}$ and outer loop cooling mass flow $W_{ext}$; cathode stoichiometry was kept constant (top); effectiveness of the intercooler model for all experimental trials and shown for various cooling mass flows in the inner and outer loop (bottom)

As shown in figure 7 the intercooler simulation results of the stationary model fit the experimental data very well. Furthermore, the heat exchanger effectiveness changes significantly within an interval of 50-95%. Figure 7 also shows the evolution of the effectiveness for constant mass flows $W_{ext}$ in the outer loop while the flow in the inner loop $W_{int}$ is varied. For constant $W_{ext}$ the effectiveness could be approximated by a constant, however still can change significantly depending on the choice of $W_{ext}$. As future controller designs possibly work with various pump speeds, a simulation model that is correct over the whole operating range of the fuel cell system is necessary. Therefore, the effectiveness is modeled as in [10] being dependent on cooling mass flows. For the dynamic simulation model parameters such as manifold, cathode and anode volumes and pipe coolant masses were determined by the system geometry and data provided by the manufacturer.

## IV. Cooling Controller Architecture

For the design of a stack inlet cooling temperature control the fuel cell system is considered a stack current dependent heat source generating a heat flow into the inner cooling loop as shown in figure 1. Evaluating the cooling system model at steady state and neglecting the hydrogen compressor's influence, the steady state valve position $u_{ss}$ to reach a certain stack inlet temperature $T_{stackin,ref}$ can be obtained by (30) with the cooler temperate $T_{cooler}$.

$$u_{ss} = \frac{\dot{Q}_{FC}}{C_c\left(\frac{\dot{Q}_{FC}}{C_h} - \frac{\dot{Q}_{FC}}{\varepsilon C_{\min}} + \frac{\dot{Q}_{FC}}{C_c} + T_{stackin,ref} - T_{cooler}\right)} \tag{30}$$

An estimation of the thermal load is obtained by (31) with the actual electrical power $P_{stack} = U_{stack} I_{stack}$ and a cell voltage corresponding to the lower heating value (LHV) of hydrogen as the stack is partly cooled by evaporation of product water in the cathode. The cooler temperature $T_{cooler}$ is being measured. The heat exchanger effectiveness $\varepsilon$ and heat capacity flows $C_h$, $C_c$ and $C_{min}$ are obtained by (25)-(26) using the measured cooling mass flows $W_{int}$ and $W_{extIC}$.

$$\dot{Q}_{FC} = U_{LHV} n_{cells} I_{stack} - P_{stack} \tag{31}$$

The control law proposed is a combination of the nonlinear feedforward control and a linear proportional and integral controller with an anti-windup to prevent integrator windup (32). The anti-windup circuit is active for controller outputs greater than 100% ($a_{windup}$=100%-$u$) and outputs less than 0% ($a_{windup}$ = 0%-$u$) and is inactive otherwise ($a_{windup}$=0). The controller gains $k_p>0$ and $k_i>0$ add with a negative sign as shown in (32) as the cooling valve needs to open for negative control errors ($T_{stackin} > T_{stackin,ref}$) and to close for positive ones.

$$u = u_{ss} - k_p\left(T_{stackin}^{ref} - T_{stackin}\right) - k_i \int T_{stackin,ref} - T_{stackin} - a_{windup} dt \tag{32}$$

A constant cooling mass flow $W_{ext}$ in the outer loop is set for the controller. Increasing the cooling mass flow would improve the cooling system dynamics as states in (21). Higher mass flows reduce the time constants for temperature in the pipe volumes. Higher pump speeds, however, result in higher power consumption. Nevertheless, the stack temperature can be set by either actuating the cooling valve or actuating the pump within certain limits set by the intercooler. This circumstance can be exploited for future control designs such that an optimal balance between pump and valve is found to optimize for power consumption or time. Here, the cooling mass flow $W_{ext}$ is set constant.

## V. Simulation Results

The simulation model is developed and run in Matlab/Simulink®. The controller for stack inlet cooling temperature is connected with the nonlinear fuel cell system model. The simulation was run for a stack cooling reference temperature of 55°C and high cathode stoichiometry. Figure 8 shows the simulation results of three controller variants:

(A) PI-control activated, feedforward control deactivated

(B) PI-control deactivated and feedforward control activated

(C) PI- and feedforward control activated.

For a constant stack cooling reference temperature of 55°C a stack current profile as shown in figure 8 was taken to test the controller for different thermal loads. With a pure feedforward control (type B) stack temperature in steady state is close to the reference temperature. The control behavior is further improved by a linear PI-controller (type C). The temperature matches the reference in steady state and under- as well as overshoots are less than in the case of a linear controller without feedforward control (type A).

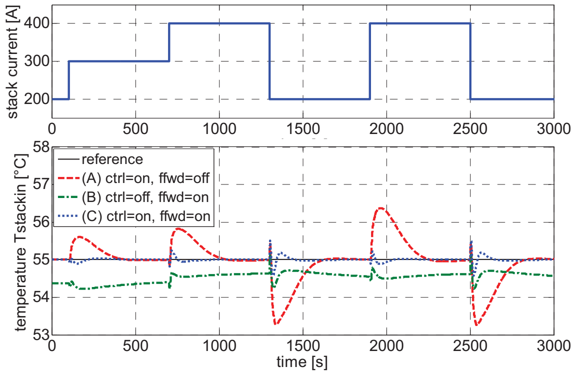

Figure 8. Simulation results of stack cooling controller for 3 controller configurations; stack current profile (top), stack cooling temperature (bottom)

## VI. Conclusion

A polymer electrolyte membrane fuel cell system electrically connected to an ohmic electronic load is connected to a coupled double-loop-cooling system with two different coolants of different specific heat capacity. The cooling loops are interconnected by a counter-flow heat exchanger (intercooler). The entire system model is derived based on physical principals and has been modeled in Matlab/Simulink®. The fuel cell system model has been fit to experimental data with very good agreement. The intercooler is modeled by the effectiveness NTU method by which a static nonlinear model is obtained. This model is valid over the entire operating range of the fuel cell system. Outlet temperatures are calculated explicitly based on input variables such as temperatures and mass flows. The intercooler model has been fit to experimental data and shows very good agreement over the entire operating range. A linear PI-controller with nonlinear feedforward control is proposed to control for stack inlet cooling temperature. The temperature controller is implemented in the nonlinear simulation model. The fuel cell and cooling system model will by used for future controller designs such as for an optimal change of stack temperature operating points or for an optimal system heat up.

TABLE I. Fuel Cell System Model Parameters

| Parameter | Description | Value |
|---|---|---|
| $M_{H2O}$ | molar mass of water | 18.0153 g/mol |
| $M_{O2}$ | molar mass of oxygen | 31.9988 g/mol |
| $M_{N2}$ | molar mass of nitrogen | 28.0134 g/mol |
| $M_{H2}$ | molar mass of hydrogen | 2.01588 g/mol |
| $R_v$ | gas constant of vapor | 461.5 J/kg/K |
| $R_{O2}$ | gas constant of oxygen | 259.8 J/kg/K |
| $R_{N2}$ | gas constant of nitrogen | 296.8 J/kg/K |
| $R_{H2}$ | gas constant of hydrogen | 4124.49 J/kg/K |
| $R_{air}$, $R_{oda}$ | gas constant of air, ODA | 287.058 J/kg/K |
| $F$ | Faraday’s constant | 96485.3 C/mol |
| $c_{air}$, $c_{oda}$ | specific heat capacity of air, ODA | 1004.7 J/kg/K |
| $c_l$ | specific heat capacity of water | 4181.9 J/kg/K |
| $c_v$ | specific heat capacity of vapor | 1864.6 J/kg/K |
| $h_o$ | enthalpy of evaporation | 2500.9×10$^3$ J/kg |
| $n_{cells}$, $A_{sfc}$ | number of cells in the stack, active surface area | |
| $d_m$ | membrane thickness | |
| $V_{im}$, $V_{om}$, $V_{ca}$, $V_{an}$ | volume of inlet and outlet manifold, stack cathode and anode | |
| $C_{st}$ | fuel cell stack heat capacity | |
| $c_{int}$, $c_{ext}$ | coolant specific heat capacity in the inner and outer cooling loop | |
| $W_i$ | mass flow leaving cathode and anode (*i=ca, an*), in- and outlet manifold (*i=im,om*), mass flow controller (*i=MFC*) | |
| $W_{i,oda}$, $W_{i,l}$, $W_{i,v}$ | mass flow of ODA, liquid water and vapor in cathode and outlet manifold (*i=ca, om)* | |
| $W_{int}$, $W_{ext}$ | coolant mass flow inner and outer cooling loop | |
| $m_{pipe,i}$, $m_{cooler}$ | mass of coolant in pipe *i* (*i=IL1, IL2, OL1, OL2*), mass of coolant in the cooler | |
| $p_i$ | pressure in volume *i* (*i=im, ca, an, om*) | |
| $m_{i,H2O}$ | mass of total water in volume *i* (*i=ca, an, om*) | |
| $m_{i,l}$ | condensate mass in *i* (*i=ca, an, om*) | |
| $m_{O2}$, $m_{N2}$ | mass of oxygen, nitrogen in cathode | |
| $m_{pipe,i}$,$m_{cooler}$ | coolant mass in *i* (*i=IL1, IL2, OL1, OL2)* and cooler | |
| $p_{O2}$, $p_{N2}$, $p_{H2}$, $p_{i,v}$ | partial pressure of oxygen, nitrogen, hydrogen and vapor in cathode, anode and outlet manifold (*i=ca, an, om*) | |
| $p_{amb}$, $T_{amb}$ | ambient pressure and temperature | |
| $T_i$ | temperature in volume *i* (*i=im, stack, om*) | |
| $T_{pipe,i}$, $T_{cooler}$ | temperature in pipe *i* (*i=IL1, IL2, OL1, OL2)* and cooler | |
| $T_{MFC}$, $T_L$ | time constant of mass flow controller, electrical load | |
| $k_{cooler}$ | heat transfer coefficient of the cooler | |
| $k_{im}$, $k_{om}$, $k_{ca}$, $k_{an}$ | mass flow coefficients for inlet- and outlet manifold, cathode and anode | |
| $\zeta_1,\ldots\zeta_4$ | coefficients for stack voltage activation loss | |
| $b_1,\ldots b_3$ | coefficients for stack voltage ohmic loss | |

# Counter-examples Design to Global Convergence of Maximum Likelihood Estimators

Yiqun Zou, Xiafei Tang and Zhengtao Ding

***Abstract*— MLE(Maximum Likelihood Estimation) is widely applied in system identification because of its consistency, asymptotic efficiency and sufficiency. However gradient-based optimization of the likelihood function might end up in local convergence. To overcome this difficulty, the non-local-minimum conditions are very useful. Here we suggest a heuristic method of constructing local minimum examples for ARMAX, ARARMAX and BJ models. Based on them the derivation of non-local-minimum conditions can be inspired by analyzing these examples.**

## I. INTRODUCTION

Many methods have been presented in the area of system identification, such as **MLE**[1][9], frequency domain analysis[11] and subspace method[12]. Amongst them, maximum likelihood estimation is one of the most popular approaches.

The idea of **MLE** introduced by [7] and further proven by [14] is to obtain the maximum likelihood estimate $\hat{\theta}_{ML}$ through maximizing the likelihood function or minimizing its corresponding natural negative logarithmic form. An efficient method is gradient descent search [9] which is applied extensively in optimization. However the if the landscape of the objective function has at least one local minimum, the gradient search may get stuck in local convergence when badly initialized. In this case, the **MLE** will produce wrong system information. Hence so-called non-local-minimum conditions[15] have been developed to judge whether there exists any local minimum.

**N.B.** To clarify the difference between the global and local minimum, here we refer the local minimum to the "false" non-global minimum as in [9].

An innovative method to derive non-local-minimum conditions can be described as follows. First of all, we design so-called "local minimum examples", i.e. the particular model structures with local minima. Secondly, via tuning the model dynamics or the input signals etc of such examples in simulation, the condition which affects the local minimum existence can be tested. At last we analyze such condition theoretically in order to derive the corresponding non-local-minimum condition. In this paper we only look at the first step and make some suggestions on the design of local minimum examples.

The structure of this paper is organized as follows. Next section explains the background of **MLE**. In section 3 the general methodology of the construction of local minimum examples is provided. Section 4 shows details of local minimum examples construction for open loop **OE**, **ARMAX**, **ARARMAX** and **BJ** models respectively. In section 5, simulation examples for each model above are given. Section 6 summarizes our contributions and points out the future works.

## II. BACKGROUND OF MAXIMUM LIKELIHOOD ESTIMATION

To illustrate the concept of **MLE**, Ljung [9] lets the observations represented by the random variable $y^N = (y(1),\, y(2),\, \ldots,\, y(t),\, \ldots,\, y(N))$ which takes values in $R^N$ and the **PDF** (**P**robability **D**ensity **F**unction) of $y^N$ by $f_y(\hat{\theta}, y^N)$. If the observed value of $y^N$ is $y_*^N$, the probability that the observation should take the value $y_*^N$ is proportional to

$$f_y(\hat{\theta}, y_*^N) \tag{1}$$

This is a deterministic function of $\hat{\theta}$ which is known as *the likelihood function*. A reasonable estimator $\hat{\theta}$ or explicitly $\hat{\theta}_{ML}$ can be chosen so that the observed event becomes "as likely as possible". That is

$$\hat{\theta}_{ML}(y_*^N) = \arg\max_{\hat{\theta}} f_y(\hat{\theta}, y_*^N) \tag{2}$$

where the maximization is performed for fixed $y_*^N$. This function is known as *maximum likelihood estimator*.

Such an estimator is reasonable because of its three advantages: firstly it provides a consistent estimate asymptotically, i.e.

$$\hat{\theta}_{ML} \to \theta \quad \text{with probability } 1 \tag{3}$$

for different model structures, e.g. [2], [4]. This property is known as consistency [14]. Secondly the covariance of $\hat{\theta}_{ML}$ is lower bounded by the inverse of Fisher information matrix, i.e.

$$E[\hat{\theta}_{ML} - \theta][\hat{\theta}_{ML} - \theta]^T \geq (-E\left[\frac{d^2}{d\hat{\theta}^2} \log f_y(\hat{\theta}, y^N)|_{\hat{\theta}=\theta}\right])^{-1} \tag{4}$$

Z. Ding is with Control Systems Centre, School of Electrical and Electronic Engineering, University of Manchester, M13 9PL, UK Email: zhengtao.ding@postgrad.manchester.ac.uk

978-1-4673-1560-9/12/$31.00 ©2012 IEEE

where the equality holds asymptotically. This property is known as asymptotic efficiency [5]. Here $E$ represents the mathematical expectation. Thirdly assume $S(y^N)$ is a sufficient statistic. According to the **Factorisation Theorem**, (1) can be rewritten to

$$f_y(\hat{\theta}, y_*^N) = \Psi(S(y_*^N), \hat{\theta})h(y_*^N) \quad (5)$$

and further transformed into its logarithmic form

$$\log f_y(\hat{\theta}, y_*^N) = \log\Psi(S(y_*^N), \hat{\theta}) + \log h(y_*^N) \quad (6)$$

Maximizing $f_y(\hat{\theta}, y_*^N)$ with respect to $\hat{\theta}$ is equivalent to maximising $\log\Psi(S(y_*^N), \hat{\theta})$ with respect to $\hat{\theta}$. This implies $f_y(\hat{\theta}, y^N)$ depends on $y^N$ through every sufficient statistic $S(y^N)$. This property of **MLE** is sufficiency [7].

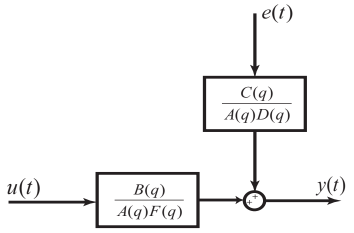

Fig. 1. General Linear Model Structure of **SISO** Open Loop Systems

In the scope of this paper only **MLE** in open loop is considered. In Fig.1, a general open loop process is shown. We assume the system dynamics can be described by the common family of model structures[9]

$$A(q)y(t) = \frac{B(q)}{F(q)}u(t) + \frac{C(q)}{D(q)}e(t) \quad (7)$$

We also assume that the estimate model is governed by

$$\hat{A}(q)y(t) = \frac{\hat{B}(q)}{\hat{F}(q)}u(t) + \frac{\hat{C}(q)}{\hat{D}(q)}\varepsilon(t, \hat{\theta}) \quad (8)$$

where the polynomials $\hat{A}(q)$, $\hat{B}(q)$, $\hat{C}(q)$, $\hat{D}(q)$ and $\hat{F}(q)$ are rational functions characterized by

$$\hat{A}(q) = 1 + \hat{a}_1 q^{-1} + \ldots + \hat{a}_{n_a} q^{-n_a} \quad (9)$$

$$\hat{B}(q) = \hat{b}_1 q^{-1} + \ldots + \hat{b}_{n_b} q^{-n_b} \quad (10)$$

$$\hat{C}(q) = 1 + \hat{c}_1 q^{-1} + \ldots + \hat{c}_{n_c} q^{-n_c} \quad (11)$$

$$\hat{D}(q) = 1 + \hat{d}_1 q^{-1} + \ldots + \hat{d}_{n_d} q^{-n_d} \quad (12)$$

$$\hat{F}(q) = 1 + \hat{f}_1 q^{-1} + \ldots + \hat{f}_{n_f} q^{-n_f} \quad (13)$$

In the notations above, $u(t)$, $y(t)$ and $e(t)$ are the input, output and noise signal respectively. The super-index "^" represents the estimates. Combining (7) and (8), the one-step-ahead prediction error $\varepsilon(t, \hat{\theta})$ can be expressed as

$$\varepsilon(t, \hat{\theta}) = \frac{\hat{D}(q)}{\hat{C}(q)}(\frac{\hat{A}(q)B(q)}{A(q)F(q)} - \frac{\hat{B}(q)}{\hat{F}(q)})u(t) + \frac{\hat{A}(q)C(q)\hat{D}(q)}{A(q)\hat{C}(q)D(q)}e(t) \quad (14)$$

Its generation is shown in Fig. 2. The estimate coefficient vector $\hat{\theta} = [\hat{a}_1 \ldots \hat{a}_{n_a} \, \hat{b}_1 \ldots \hat{b}_{n_b} \, \hat{c}_1 \ldots \hat{c}_{n_c} \, \hat{d}_1 \ldots \hat{d}_{n_d} \, \hat{f}_1 \ldots \hat{f}_{n_f}]^T$ and the true parameter $\theta$ in a similar manner are defined. It is worthwhile to point out that if necessary we will also use the notations $[A(q)\, B(q)\, C(q)\, D(q)\, F(q)]$ and $[\hat{A}(q)\, \hat{B}(q)\, \hat{C}(q)\, \hat{D}(q)\, \hat{F}(q)]$ to represent $\theta$ and $\hat{\theta}$ respectively.

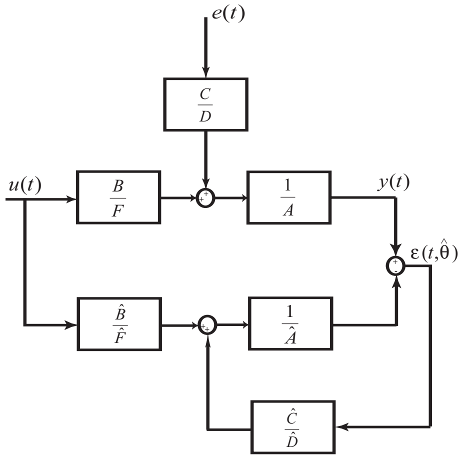

Fig. 2. Generation of Model Based One-step-ahead Prediction Error $\varepsilon(t, \hat{\theta})$

| Model Structures | Characteristics |
|---|---|
| **ARMAX**[2] | $D(q) = F(q) = 1$ |
| **ARARMAX**[9] | $F(q) = 1$ |
| **OE**[6] | $A(q) = C(q) = D(q) = 1$ |
| **BJ**[4] | $A(q) = 1$ |

TABLE I
DEFINITIONS OF MODEL STRUCTURES

To clarify different model structures used in this paper, their definitions are provided in TABLE I. According to it, **ARMAX** and **OE** models can be produced by **ARARMAX** and **BJ** models via choosing $D(q) = 1$ and $C(q) = D(q) = 1$ respectively. For reference convenience, we omit the forward shift operator $(q)$ and its frequency domain interpretation $(e^{j\omega})$ when there is no misunderstanding. In addition, we define an auxiliary notation

$$d(\hat{X}, \hat{Y}) \quad = \quad X(q)\hat{Y}(q) - \hat{X}(q)Y(q) \quad (15)$$

where $\hat{X}(q)$ and $\hat{Y}(q)$ are the corresponding estimate polynomials of $X(q)$ and $Y(q)$.

The following assumptions are postulated through out this paper:
(AP1). The input $u(t)$ persistently exciting of relevant system orders is deterministic and periodic or filtered white noise [13].
(AP2). The noise signal $e(t)$ and true prediction error $\varepsilon(t, \theta)$ are identical independent distributed subject to $N(0, \sigma^2)$ where the variance is known.
(AP3). The true polynomials $A$, $C$, $D$, $F$ and estimated

polynomials $\hat{A}$, $\hat{C}$, $\hat{D}$, $\hat{F}$ all have the roots inside the unit circle.
(AP4). The orders of estimate polynomials are equal to the true ones, i.e. $n_a = \hat{n}_a$, $n_b = \hat{n}_b$, $n_c = \hat{n}_c$, $n_d = \hat{n}_d$ and $n_f = \hat{n}_f$.
(AP5). The number of data $N$ goes to infinity.

Next let us derive the likelihood function for $y^N$ which is described by the estimate model (8). Assume $\varepsilon(t,\hat{\theta})$ has the **PDF** $f_e(\varepsilon(t,\hat{\theta}),t,\hat{\theta})$. According to the joint **PDF** for the observations $y^N$ provided in **Lemma 5.1** in [9], the likelihood function turns to be

$$f_y(\hat{\theta},y^N) = \prod_{t=1}^{N} f_e(\varepsilon(t,\hat{\theta}),t,\hat{\theta}) \tag{16}$$

Maximizing (16) is equivalent to minimizing

$$-\frac{1}{N}\log(f_y(\hat{\theta},y^N)) = -\frac{1}{N}\sum_{t=1}^{N}\log f_e(\varepsilon(t,\hat{\theta}),t,\hat{\theta}) \tag{17}$$

When $\hat{\theta} = \theta$ holds, i.e. $\varepsilon(t,\hat{\theta}) = e(t)$. Then the random function $f_e(\varepsilon(t,\hat{\theta}),t,\hat{\theta})$ turns to be a Gaussian density function. Thus (17) can be simplified into the loss function

$$V_N(t,\hat{\theta}) = \frac{1}{2N}\sum_{t=1}^{N}\varepsilon^2(t,\hat{\theta}) \tag{18}$$

The value of $V_N(t,\hat{\theta})$ is stochastic with fixed $\hat{\theta}$ and a small $N$. It is hard to analyze the property of $V_N(t,\hat{\theta})$ in this case. In order to avoid this difficulty, combining (AP5) we introduce the asymptotic loss function

$$V(\hat{\theta}) = \lim_{N\to\infty} V_N(t,\hat{\theta}) \quad \text{with probability 1} \tag{19}$$

in the following instead of $V_N(t,\hat{\theta})$. Note that (AP1), (AP2), (AP3) and (AP4) ensure the existence of $V(\hat{\theta})$ [13]. For convenience we replace $\lim_{N\to\infty}\frac{1}{N}\sum_{t=1}^{N}$ with the symbol $\bar{E}$. Then

$$V(\hat{\theta}) = \frac{1}{2}\bar{E}\varepsilon^2(t,\hat{\theta}) \tag{20}$$

holds. Since

$$\bar{E}\varepsilon^2(t,\hat{\theta}) \geq \bar{E}\varepsilon^2(t,\theta) \tag{21}$$

stands under (AP2), maximum likelihood estimator can be obtained by the minimization of (20).

## III. Methodology

The methodology of local minimum design originates from [8]. Goodwin *et al* define the **DEPEN**(**D**ecreasing **E**uclidean **P**arameter **E**rror **N**orm) region as $\Gamma$ in parameter space. Its elements $\hat{\theta}$ are those which will get closer to the true parameter $\theta$ in the Euclidean sense when an infinitesimal step is taken along the negative gradient direction of $V(\hat{\theta})$. For such region, it holds that

***Lemma 1***[8]. $\hat{\theta} \in \Gamma$ *if and only if the inner product between* $\tilde{\theta} = \hat{\theta} - \theta$ *and* $V'(\hat{\theta})$ *is positive, i.e.*

$$\tilde{\theta}^T V'(\hat{\theta}) > 0 \tag{22}$$

**Proof:** Let $\hat{\theta}_i$ denote the current estimate. The **SDS**(**S**teepest **D**escent **S**earch) can be expressed as

$$\hat{\theta}_{i+1} = \hat{\theta}_i - \zeta_i V(\hat{\theta}_i) \tag{23}$$

[9] where $\zeta_i$ is the step size. Subtracting $\theta$ from both sides gives

$$\tilde{\theta}_{i+1} = \tilde{\theta}_i - \zeta_i V(\hat{\theta}_i) \tag{24}$$

Squaring both sides provides

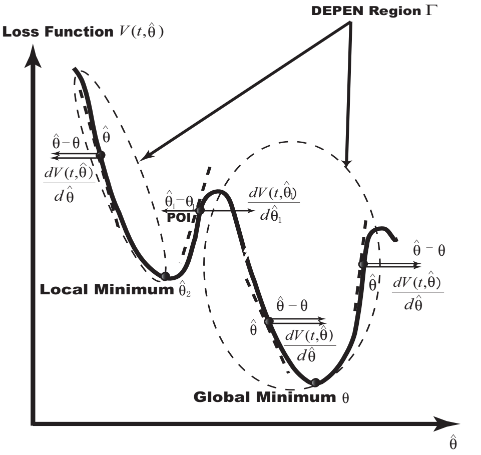
$$\tilde{\theta}_{i+1}^T\tilde{\theta}_{i+1} = \tilde{\theta}_i^T\tilde{\theta}_i - 2\zeta_i\tilde{\theta}_i^T V'(\hat{\theta}_i) + \zeta_i^2(V'(\hat{\theta}_i))^T V'(\hat{\theta}_i) \tag{25}$$

When $\zeta_i$ is sufficiently small, we could neglect the last term on the right side of (25) and prove the lemma. □

According to (22), those $\hat{\theta}$ circled by the dash-line belong to the **DEPEN** region in Fig. 3 since $\tilde{\theta}$ and $V'(\hat{\theta})$ point at the same direction. Conversely, **SDS** starting off at points like $\hat{\theta}_1$ which satisfies

$$\tilde{\theta}_1^T V'(\hat{\theta}_1) \leq 0 \tag{26}$$

could *possibly* converge to the nearest local minimum $\hat{\theta}_2$. We call such $\hat{\theta}_{ini}$ *point of interest* or **POI** and the dash-line circled landscape constituted by **POI** the *region of interest*. To sum up, the construction of local minimum examples can be transformed into the design of **POI** satisfying (26) followed used in **SDS** as the initial value.



DEPEN Region Γ

**Remarks:**
(1). In Fig. 3, the directions of the two arrows starting at $\hat{\theta}$ represent the sign of $\tilde{\theta}$ and $V'(\hat{\theta})$ respectively which are both scalars on the two-dimensional plot.

(2). The search may also possible converge to other kinds of stationary point, such as the saddle point.

## IV. Local Minimum Examples Design

In this section we review how to construct local minimum examples for **OE** models[13] first and then implement the method described in section 3 to design local minimum examples for **ARMAX**, **ARARMAX** and **BJ** models.

For open loop **OE** models

$$y(t) = \frac{B}{F}u(t) + e(t) \tag{27}$$

according to the form of the prediction error $\varepsilon(t,\hat{\theta})$ in (14), its asymptotic loss function can be derived as

$$V(\hat{\theta}) = \frac{1}{2}\bar{E}\left[\left(\frac{B}{F} - \frac{\hat{B}}{\hat{F}}\right)u(t)\right]^2 + \frac{1}{2}\bar{E}[e(t)]^2 \tag{28}$$

Söderström suggested that optimizing (28) with respect to $\hat{b}$ firstly, $V(t,\hat{\theta})$ can be transformed into the pseudo-asymptotic function[**?**]

$$\tilde{V}(\hat{f}) = \frac{1}{2}(V_0 - V_1(\hat{f})^T V_2(\hat{f})^{-1} V_1(\hat{f})) \tag{29}$$

where

$$V_0 = \bar{E}\left[\frac{B}{F}u(t)\right]^2 + \bar{E}[e(t)]^2 \tag{30}$$

$$V_1(\hat{f}) = \bar{E}[\frac{B}{F}u(t)]\left[\frac{1}{\hat{F}}u(t-i)\right] \qquad 1 \le i \le n_b \tag{31}$$

$$V_2(\hat{f}) = \bar{E}\left[\frac{1}{\hat{F}}u(t-i)\right]\left[\frac{1}{\hat{F}}u(t-j)\right]^T \qquad 1 \le i,j \le n_b \tag{32}$$

Here $\hat{f} = [\hat{f}_1 \; \dots \; \hat{f}_{n_f}]^T$. $\left[\frac{1}{\hat{F}}u(t-i)\right]$ and $\left[\frac{1}{\hat{F}}u(t-j)\right]$ are $n_f$-column vectors. Since $V_2(\hat{f})$ is positive definite, the following inequality

$$\tilde{V}(\hat{f}) \le \frac{1}{2}V_0 \tag{33}$$

always holds. The equality only holds when $V_1(\hat{f}) = 0$. If the curve of $\tilde{V}(\hat{f}) = \frac{1}{2}V_0$ bisects the stability region of $\hat{f}$, normally there is at least one minimum at each side of the curve.

The **POI** of **ARMAX** and **BJ** models are more or less related to the local minimum of the **OE** models. This can be seen as follows.

*Design of **POI** for **ARMAX** models*: Assume the following **OE** model

$$y(t) = \frac{B(q)}{F(q)}u_1(t) + e(t) \tag{34}$$

has a local minimum at $[\hat{B}_1 \; \hat{F}_1]$. Then we design the provisional **ARMAX** model

$$A_p(q)y(t) = B_p(q)u_p(t) + C_p(q)e(t) \tag{35}$$

where

$$\begin{cases} A_p(q) = F(q) + \delta(q), \\ B_p(q) = B(q), \\ C_p(q) = F(q), \\ u_p(t) = \alpha u_1(t). \end{cases} \tag{36}$$

Here $\alpha$ is a positive coefficient attached before the input signal to adjust the **SNR**(**S**ignal-to-**N**oise-**R**atio)[**?**][**?**] and $\delta(q)$ is a deviation polynomial

$$\delta_1 q^{-1} + \delta_2 q^{-2} \dots + \delta_{n_a} q^{-n_a} \tag{37}$$

introduced to avoid the overlap between **OE** and **ARMAX** models. The selection of it yields to

$$\forall\sqrt{\delta_1^2 + \dots + \delta_{n_a}^2} < \xi \;\; \text{s.t.} \;\; \tilde{\theta}^T V'(t,\hat{\theta}) \le 0 \, \text{at} \; [\hat{F}_1 \; \hat{B}_1 \; \hat{F}_1] \tag{38}$$

where $\xi$ is a small positive scalar. **SDS** initialized at $\hat{\theta} = [\hat{F}_1 \; \hat{B}_1 \; \hat{F}_1]$ probably converges to the nearby local minimum $[\hat{A}_2 \; \hat{B}_2 \; \hat{C}_2]$.

*Design of **POI** for **ARARMAX** models:* Suppose the **ARMAX** model (35) has a local minimum $[\hat{A}_2 \; \hat{B}_2 \; \hat{C}_2]$. For the following **ARARMAX** model

$$A_p y(t) = B_p u_3(t) + \frac{C_p}{D_p}e(t), \tag{39}$$

where the input signal is

$$u_3(t) = \frac{1}{D_p}u(t), \tag{40}$$

the equalities

$$\begin{aligned} \tilde{\theta}^T V'(\hat{\theta}) &= \frac{1}{\pi}\int_0^{\pi} \Re(\frac{C}{\hat{C}})(|G_1|^2 \Phi_{uu}(\omega) + |G_2|^2\sigma^2)d\omega \\ &= 0 \end{aligned} \tag{41}$$

[8][**?**] hold at $\hat{\theta} = [\hat{A}_2 \; \hat{B}_2 \; \hat{C}_2 \; D_p]$. Here

$$G_1 = \frac{d(\hat{B},\hat{A})}{A\hat{C}} \qquad G_2 = \frac{d(\hat{C},\hat{A})}{A\hat{C}} \tag{42}$$

Therefore **SDS** initialized at such point converges to the nearby stationary point $[\hat{A}_3 \; \hat{B}_3 \; \hat{C}_3 \; \hat{D}_3]$. To ensure it is a local minimum, we only apply those $D_p$ which let the Hessian matrix of the stationary point positive definite.

*Design of **POI** for **BJ** models:* It also starts from (34) which has the local minimum $[\hat{B}_1 \; \hat{F}_1]$. For the following **BJ** model

$$y(t) = \frac{B}{F}u_2(t) + \frac{C}{D}e(t), \tag{43}$$

where $B$ and $F$ are the same polynomials as in (34) and the input signal

$$u_2(t) = \frac{C}{D}u_1(t). \tag{44}$$

The inner product of $\tilde{\theta}$ and $V'(\hat{\theta})$ is equal to zero at $[\hat{B}_1 \; C \; D \; \hat{F}_1]$. Hence **SDS** initialized at this point $\hat{\theta} = [\hat{B}_1 \; C \; D \; \hat{F}_1]$ converges to the nearby stationary point $[\hat{B}_2 \; \hat{C}_2 \; \hat{D}_2 \; \hat{F}_2]$ differing from the global minimum. To ensure it is a local minimum point, again we only adopt those polynomials $C$ and $D$ which make the Hessian matrix of $[\hat{B}_2 \; \hat{C}_2 \; \hat{D}_2 \; \hat{F}_2]$ positive definite.

## V. Simulation Examples

In this section we give a local minimum example for each model above. In all examples, the length of all data points $N$ is 10000. Noise signal $e(t)$ has unit variance. For **ARMAX**, **ARARMAX** and **BJ** example, **SDS** based on (23) initialized at the **POI** is applied iteratively until the condition

$$\frac{|V(\hat{\theta}_i) - V(\hat{\theta}_{i-1})|}{V(\hat{\theta}_i)} < 0.0005 \tag{45}$$

is met or a maximum iteration number 20 is reached.

**Example 1:** The dynamics of the **OE** model is given as

$$\begin{cases} B = q^{-1} \\ F = 1 - 1.2q^{-1} + 0.36q^{-2} \end{cases} \tag{46}$$

The input signal is

$$u_1(t) = (1 - 0.72q^{-2} + 0.1296q^{-4})v_1(t) \tag{47}$$

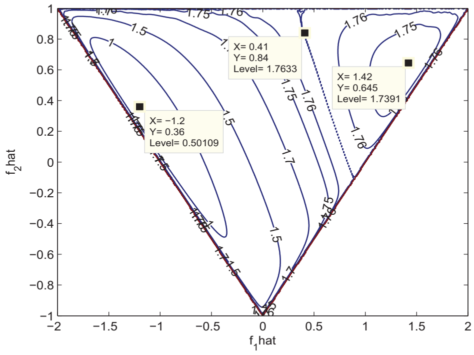

Fig. 4. The Contour of $\tilde{V}(\hat{f})$ for Example 1

Here $v_1(t)$ is i.i.d Gaussian signal with unit variance. The contour of $\tilde{V}(\hat{f})$ is shown in Fig. 4. The curve $\tilde{V}(\hat{f}) =$ 1.76619 bisects the stability triangle where the coefficients $\hat{f}_1$ and $\hat{f}_2$ satisfy [10]

$$-1 < \hat{f}_2 < 1 \tag{48a}$$

$$\hat{f}_1 - 1 < \hat{f}_2 \tag{48b}$$

$$-\hat{f}_1 - 1 < \hat{f}_2 \tag{48c}$$

into two subsets. Each subset has one minimum. They are

$$\theta = [1 \ -1.200 \ 0.360]^T \quad \text{(global minimum)} \tag{49a}$$

$$\hat{\theta}_1 = [-0.121 \ 1.419 \ 0.670]^T \quad \text{(local minimum)} \tag{49b}$$

**Example 2:** Given an **ARMAX** model where

$$\begin{cases} A_p(q) = (1 - 1.2q^{-1} + 0.36q^{-2}) + \delta(q) \\ B_p(q) = q^{-1} \\ C_p(q) = 1 - 1.2q^{-1} + 0.36q^{-2} \end{cases} \tag{50}$$

The input signal of the system is

$$u_p(t) = 0.3u_1(t) \tag{51}$$

where $u_1(t)$ is the input signal used in example 1. At

$$\hat{\theta} = [1.419 \ 0.670 \ -0.121 \ 1.419 \ 0.670]^T \tag{52}$$

selecting

$$\delta(q) = 0.2q^{-1} + 0.09q^{-2} \tag{53}$$

makes

$$\tilde{\theta}^T V'(\hat{\theta}) = -0.0305 \tag{54}$$

which implies (38) satisfied. Starting from (52), **SDS** converges to the following stationary point

$$\begin{cases} \hat{A}_2 = 1 + 1.304q^{-1} + 0.5435q^{-2} \\ \hat{B}_2 = -0.1035q^{-1} \\ \hat{C}_2 = 1 + 1.386q^{-1} + 0.6022q^{-2} \end{cases} \tag{55}$$

after four iterations. Its Hessian matrix

$$\begin{bmatrix} 7.07 & -5.99 & 0.14 & -7.94 & 6.50 \\ -5.99 & 7.07 & -0.05 & 7.16 & -7.94 \\ 0.14 & -0.05 & 0.33 & -0.16 & 0.02 \\ -7.94 & 7.16 & -0.16 & 9.11 & -7.92 \\ 6.50 & -7.94 & 0.02 & -7.92 & 9.11 \end{bmatrix}$$

is positive definite. The trace of loss function in **SDS** is shown in Fig. 5.

**Example 3:** For such **ARARMAX** model which has the same $A_p$, $B_p$ and $C_p$ with in example 2, we assign its $D_p$ and input signal as

$$\begin{cases} D_p = 1 + 0.8257q^{-1} \\ u_3(t) = \dfrac{1}{D_p} u_p(t) \end{cases} \tag{56}$$

**SDS** starting at $\hat{\theta} = [\hat{A}_2 \ \hat{B}_2 \ \hat{C}_2 \ D_p]$ eventually ends at the stationary point

$$\begin{cases} \hat{A}_3 = 1 + 1.312q^{-1} + 0.5464q^{-2} \\ \hat{B}_3 = -0.1035q^{-1} \\ \hat{C}_3 = 1 + 1.377q^{-1} + 0.6009q^{-2} \\ \hat{D}_3 = 1 + 0.815q^{-1} \end{cases} \tag{57}$$

after five iterations. The Hessian matrix of this point

$$\begin{bmatrix} 7.06 & -5.98 & 0.14 & -7.67 & 6.37 & 4.72 \\ -5.98 & 7.06 & -0.05 & 6.73 & -7.67 & -3.85 \\ 0.14 & -0.05 & 0.32 & -0.16 & 0.03 & 0.12 \\ -7.67 & 6.73 & -0.16 & 8.43 & -7.25 & -5.03 \\ 6.37 & -7.67 & 0.03 & -7.25 & 8.43 & 4.11 \\ 4.72 & -3.85 & 0.12 & -5.03 & 4.11 & 4.13 \end{bmatrix}$$

is positive definite. The trace of loss function in **SDS** is shown in Fig. 6.

**Example 4**: The true polynomials of this **BJ** model are

$$\begin{cases} B = q^{-1} \\ C = 1 + 0.6428q^{-1} \\ D = 1 - 0.6616q^{-1} + 0.1792q^{-2} \\ F = 1 - 1.2q^{-1} + 0.36q^{-2} \end{cases} \tag{58}$$

Its input signal is

$$u_2(t) = \frac{C}{D} u_1(t) \tag{59}$$

Let **SDS** begins at $\hat{\theta} = [\hat{B}_1 \; C \; D \; \hat{F}_1]$. After eight steps of iteration, **SDS** ends up at the following local minimum point

$$\begin{cases} \hat{B}_2 = -0.0804q^{-1} \\ \hat{C}_2 = 1 + 0.6927q^{-1} \\ \hat{D}_2 = 1 - 1.062q^{-1} + 0.4294q^{-2} \\ \hat{F}_2 = 1 + 1.398q^{-1} + 0.6252q^{-2} \end{cases} \tag{60}$$

Its Hessian matrix

$$\begin{bmatrix} 7.13 & -1.95 & -0.37 & -0.94 & -0.41 & -0.19 \\ -1.95 & 6.09 & -1.39 & 0.99 & 0.32 & -0.17 \\ -0.37 & -1.39 & 7.57 & 5.61 & 0.29 & 0.11 \\ -0.94 & 0.99 & 5.61 & 7.57 & 0.09 & -0.44 \\ -0.41 & 0.32 & 0.29 & 0.09 & 0.24 & -0.23 \\ -0.19 & -0.17 & 0.11 & -0.44 & -0.23 & 0.66 \end{bmatrix}$$

is positive definite. The trace of loss function in **SDS** is shown in Fig. 7.

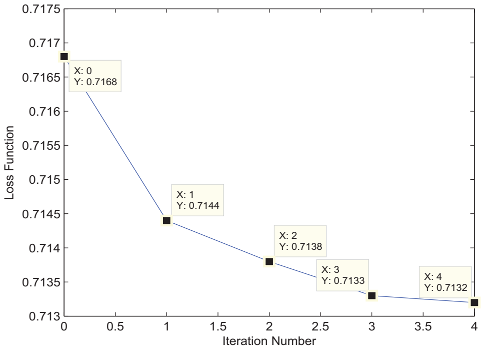

Fig. 5. Evaluation of Asymptotic Loss Function $V(\hat{\theta})$ in **SDS** for Example 2

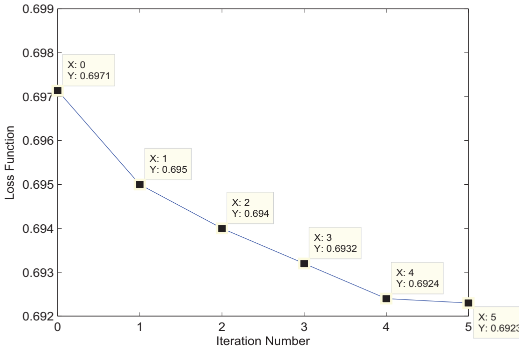

Fig. 6. Evaluation of $V(\hat{\theta})$ in **SDS** for Example 3

## VI. CONCLUSIONS AND FUTURE WORKS

In this paper, we design the **POI** followed by **SDS** to construct local minimum examples for open loop **ARMAX**, **ARARMAX** and **BJ** models. In particular, the **POI**s for **ARMAX** and **BJ** models have strong links to the local minimum in the corresponding **OE** models. Furthermore, simulation examples are also provided for each model structure above. These examples play as a key to the development of the non-local-minimum conditions in **MLE**. In the future, we will investigate the non-local-minimum conditions for these models starting by changing the examples dynamics etc.

***Abstract*—A new method for identification of structural parameters is proposed using Damped Transfer Matrices (DTM) and state vectors. A new transfer matrix is derived for continuous mass systems including the damping parameters. The state vector at a location is the sum of the internal and external contributions of displacements, forces and moments at that point, when it is multiplied with the transfer matrix, state vector at the adjacent location is obtained. The structural identification algorithm proposed here involves prediction of displacement responses at selected locations of the structure using Damped Transfer Matrix and compares them with the measured responses at the respective locations. The mean square deviations between the measured and predicted responses at all locations are minimized using a non-classical optimization algorithm, and the optimization variables are the unknown stiffness and damping parameters in the DTM. A non-classical heuristic Particle Swarm Optimization algorithm (PSO) is used, since it is especially suited for global search. This DTM algorithm with successive identification strategy is applied on one element or substructure of a structure at a time and identifies all the parameters of adjacent elements successively. The algorithm is applied on numerically simulated experiments of structures such as a cantilever and one sub-structure of a nine member frame structure. Also this algorithm is verified experimentally on a sub-structure of a fixed beam. The main advantage of this algorithm is that it can be used for the local identification in a zone in a structure without modelling the entire global structure.**

## I. Introduction

Structural identification (SI) problems typically deal with the estimation of mass, stiffness and damping properties of a structure from input/output measurements. It plays an important role in model updating and structural health monitoring. From a computational point of view, structural identification presents a challenging problem particularly when the system involves a large number of unknown parameters. SI algorithms are generally classified into frequency domain and time domain algorithms. Frequency domain SI algorithms have been developed more widely. Maia and Silva [1] presented some modal analysis techniques for identification. Ge and Lui [2] identified damage on structures like cantilever, ten story steel frame and plates by comparing natural frequencies of the undamaged and damaged structures.

Time domain algorithms are usually categorized as Classical or Non-classical methods. Ghanem and Shinozuka [3] reported few classical SI time domain algorithms such as Recursive Least Square method (RLS), Extended Kalman Filter method (EKF), maximum likelihood method, recursive instrumental variable method. Juang and Pappa [4] presented a deterministic SI algorithm based on state space model of second order system using Observer Kalman Filter Identification and Eigen Realisation Algorithm (OKID/ERA) by which all the structural properties such as mass, damping coefficient, stiffness can be identified. Some of the shortcomings of the classical methods are requirement of the calculation of derivatives; difficulty of converging to the global optima, requirement of initial values, and inability to deal with large number of variables. To overcome these drawbacks, Non-classical SI algorithms are used. A non-classical method is usually based on heuristic concepts such as Evolutionary principle (GA) or behavioural principle (PSO). Koh *et al* [5]. identified a maximum of 52 structural parameters including damping using GA with a hybrid local search method. GA directs the search toward the global optima and the local search improves the convergence. Kennedy and Eberhart [6] developed a new stochastic optimization algorithm PSO which was proved that much superior to GA and easy to configure [7]. Perez and Behdinan [8] also used PSO for a structural identification problem of 72 bar truss with good accuracy.

The computational effort of identifying a $n$ DOF system is of the order of $n^2$. Even for a modern computer, the computational speed for solving large matrices is challenging. As an alternative for this problem, transfer matrices and state vectors are used for SI algorithm. Steidel [9] derived the transfer matrix for a spring mass system and a beam element. The transfer matrix for the beam element is derived by assuming that the mass is concentrated only at end nodes and the beam element is mass less throughout its length. Meirovitch [10] determined the natural frequencies and mode shapes of a non-uniform pinned-pinned beam with ten elements using transfer matrices. Nandakumar and Shankar

978-1-4673-1560-9/12/$31.00 ©2012 IEEE

[11] used the transfer matrices derived by Steidel [9] and state vectors first in SI problem and identified successfully the parameters of cantilever and ten DOF lumped mass system. Later Tuma and Cheng [12] derived an improved transfer matrix for beam element with an assumption of the mass of the beam element is concentrated at its mass center. It is found that there is a good improvement in natural frequencies.

Nandakumar and Shankar [13] derived a transfer matrix from the consistent mass matrix of the beam element and determined higher order natural frequencies with much better accuracy than the existing lumped mass based transfer matrices. Using the same transfer matrix, stiffness parameters of structures were identified with better accuracy. However all these transfer matrices discussed have a limitation in that they can be used only for lightly damped structures/materials by ignoring its damping effect. To identify properties of highly damped structures which have significant damping, a new damped transfer matrix (DTM) including damping parameters is derived. In this paper structural parameters including damping parameters were identified using DTM by Successive Structural Identification strategy.

## II. Transfer Matrices and State Vectors

A state vector at a point in the structure is the summation of the internal response vector and external force vector. The former contains the output responses such as displacement, angular displacement and the internal forces and moments and the later contains the externally applied forces and moments. The Transfer Matrix (TM) is a square matrix which contains the structural parameters. When a state vector is multiplied with the TM, internal response vector at the adjacent location is obtained.

### *A. Transfer Matrix for Beam element*

In this section the transfer matrix for damped vibration of beams is derived. The equilibrium equation of two noded beam element is

$$[M]\ddot{x}(t) + [C]\dot{x}(t) + [K]x(t) = F(t) \tag{1}$$

where $\ddot{x}(t)$, $\dot{x}(t)$ and $x(t)$ are nodal acceleration, velocity and displacement responses vector respectively, $F(t)$ is nodal force vector. The state vector for a node on the beam element is $\{X\} = \{y(t), \theta(t), M(t), V(t)\}^T + \{0, 0, F(t), \mu(t)\}^T$, where $y(t)$ is translational displacement, $\theta(t)$ is angular displacement, $M(t)$ is bending moment, $V(t)$ is shear force, $F(t)$ is applied force and $\mu(t)$ is applied moment at that node. The damping in the beam element is modelled using Rayleigh's damping model.

$$[C] = \alpha[M] + \beta[K] \tag{2}$$

Also $\ddot{x}(t) = -\omega^2 x(t)$, $\dot{x}(t) = i\omega x(t)$. therefore, the Eq.(1) becomes,

$$F(t) = [Z]x(t) \tag{3}$$

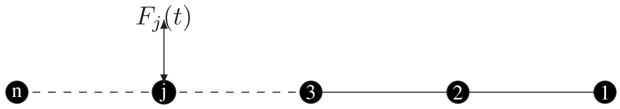

Fig. 1. Sub-structure with arbitrary point excitation

where $[Z] = (i\omega\alpha - \omega^2)[M] + (1 + i\omega\beta)[K]$. Since the beam element is in equilibrium, the Eq.(3) is written for one element

$$\begin{Bmatrix} -M_1(t) \\ -V_1(t) \\ -- \\ M_2(t) \\ V_2(t) \end{Bmatrix} = \begin{bmatrix} Z_{11} & Z_{12} & | & Z_{13} & Z_{14} \\ Z_{21} & Z_{22} & | & Z_{23} & Z_{24} \\ - & - & + & - & - \\ Z_{31} & Z_{32} & | & Z_{33} & Z_{34} \\ Z_{41} & Z_{42} & | & Z_{43} & Z_{44} \end{bmatrix} \begin{Bmatrix} y_1(t) \\ \theta_1(t) \\ -- \\ y_2(t) \\ \theta_2(t) \end{Bmatrix} \tag{4}$$

Assume the output responses and internal forces/moments at node 1 are known and external forces are zero, the force and DOF vectors in the Eq.(4) is rearranged to form state vectors $\{X\}$ in such away that $\{X_2\} = [T_d]\{X_1\}$, the transfer matrix is

$$[T_d] = \begin{bmatrix} -[Q] & [0] \\ -[S] & [I] \end{bmatrix}^{-1} \begin{bmatrix} [P] & [I] \\ [R] & [0] \end{bmatrix} \tag{5}$$

where $[P] = \begin{bmatrix} Z_{11} & Z_{12} \\ Z_{21} & Z_{22} \end{bmatrix}$, $[Q] = \begin{bmatrix} Z_{13} & Z_{14} \\ Z_{23} & Z_{24} \end{bmatrix}$, $[R] = \begin{bmatrix} Z_{31} & Z_{32} \\ Z_{41} & Z_{42} \end{bmatrix}$, $[S] = \begin{bmatrix} Z_{33} & Z_{34} \\ Z_{43} & Z_{44} \end{bmatrix}$

### *B. Transfer matrix and state vector for the global structure*

Calculation of state vector at any node of a global structure, from one known initial state vector at a given node using transfer matrices is illustrated here. For example, a portion of a structure is considered with $n$ nodes subjected to an arbitrary point excitation as shown in Fig.1. It is assumed that all elements in the state vector at the node 1 are known. The state vectors at other nodes can be calculated by successive multiplication of elemental transfer matrices. The equation to calculate internal response vector for $n^{th}$ node from internal response vector at node 1 and external force vector is obtained.

$$\{X_{ni}\} = \left(\prod_{k=1}^{n-1} [T_{(n-k),(n+1-k)}]\right)\{X_{1i}\} + \sum_{j=1}^{n-1}\left(\prod_{k=1}^{n-j} [T_{(n-k),(n+1-k)}]\right)\{X_{je}\} \tag{6}$$

For free damped vibration i.e without any external forces, as a special case the above equation can be deduced as

$$\{X_n\} = \left(\prod_{k=1}^{n-1} [T_{(n-k),(n+1-k)}]\right)\{X_1\} \tag{7}$$

In the above equation, $[T^G_{1,n}] = \prod_{k=1}^{n-1}[T_{(n-k),(n+1-k)}]$ is known as global transfer matrix.

## III. Parameter Identification by Damped Transfer Matrix Method (DTM)

The proposed DTM algorithm is used for identifying the unknown flexural rigidities (EI) of the structure assuming the masses are known. The beam is excited with a known force at a point. The elements of initial state vector is measured at one location, from which it is possible to predict the displacement at any location in the structure using successive multiplication of the DTMs, as discussed in section II-B. The mean square deviation between the predicted and measured displacements at measured locations in the structure can be minimized by Particle Swarm Optimization algorithm (PSO) with the unknown elemental $EI$ values, $\alpha$ and $\beta$ in the DTM as the optimization variables. The Successive identification strategy [13] is adopted to identify unknown parameters since it is superior in speed and accuracy for the identification of a few adjacent elements.

Since the elements of DTM are complex numbers, the elements of all predicted state vectors are complex responses except the initial state vector. Its elements are all real signals since they are measured directly. The imaginary part of the responses in the predicted state vectors is proportional to the contribution of damping property of the structure. For the lightly damped structures/materials the imaginary part of the responses is very small and hence may be neglected and only real part of the response is considered for identification. But for significantly damped structures the imaginary part of the responses is considerable, hence the complex responses are converted from Cartesian form into Polar form. Let the polar form of the responses contain magnitude ($u_e$) and phase shift ($\phi$). The number of time steps are to be shifted is calculated by the relation $t_s = \frac{\phi f_s}{\omega}$ where, the $f_s$ is sampling frequency in Hz and $\omega$ is circular frequency of excitation in r/s. The error function between measured and predicted responses is given by

$$\varepsilon = \frac{\sum_{j=1}^{L} |u_m(j) - u_e(j+t_s)|^2}{L} \tag{8}$$

where $u_m(j)$ and $u_e(j)$ are measured and estimated displacement responses respectively at $j^{th}$ time step. $L$ is the number of time steps. Then the cycle is repeated for all the pairs of adjacent measured responses and identify all unknown parameters successively. Since, the number of unknown parameters to be identified is one or few for one identification cycle, the convergence is very fast, the overall computational time is very small. This strategy is promising in the identification of local parameters in a structural member.

## IV. Numerical Examples and Results

The SI algorithm using damped transfer matrix (DTM) is applied on two numerically simulated experiments. i.e a uniform cantilever and a sub-structure of a nine member frame structure. The structure is excited by a harmonic force at a node and the acceleration responses are measured at selected nodes and converted to displacement responses by numerical integration. In all examples, measured responses are numerically simulated using Newmark's constant acceleration method. The unknown stiffnesses and damping parameters are searched by PSO algorithm within the search range of 50% to 150% of the exact values. In order to simulate the effect of noise in experiments, Gaussian random noise of 3% is added to the measured signals.

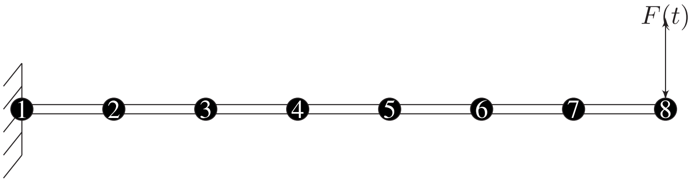

Fig. 2. Finite Element model of cantilever

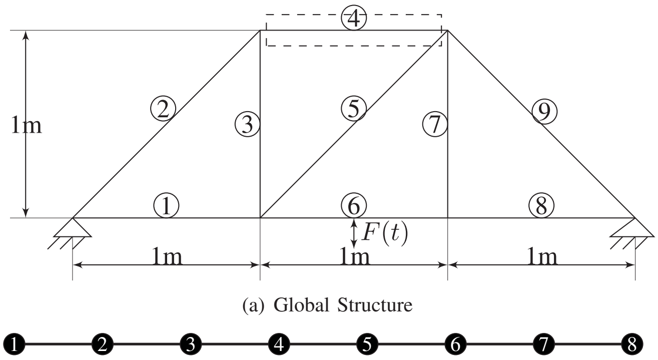
### A. Example-1: Cantilever

A steel cantilever of dimension 24.6 × 5.7 × 350 mm is fixed at its one of the end as shown in Fig.2. The Young's modulus of cantilever material is 200 GPa and its density is 7691 kg/m$^3$. It is divided into seven finite elements of length 50mm each. The flexural rigidity ($EI$) of each element is 75.93 N.m$^2$. The damping constants $\alpha$ and $\beta$ are 20.77 and 5.71×10$^{-5}$ respectively. The free end is excited by a harmonic input force of $1.5sin(2\pi 10t)$ N. The first natural frequency of the beam is 38.33 Hz. The effect of the damping was accounted by Rayleigh's damping with modal damping ratio of 5% at its first two modes. Since the bending moment and shear force responses are zero at the free end, the initial state vector is formed at the free end. The translational responses are measured at all nodes and angular response is measured at the free end only. From the initial state vector the unknown parameters are identified using DTM successively with PSO parameters of swarm size 50 and 50 iterations in each identification cycle with variable inertia weight varies from 0.9 to 0.4. The identification algorithm is repeated with translational responses measured at nodes 3, 5, 7 and 8. The cantilever is divided into four substructures from nodes (1-3), (3-5), (5-7) and (7-8) and parameters are identified in each substructure successively. This problem was repeated with 3%

TABLE I
Percentage of error in identified results of cantilever

| Element | % of Error | | | |
|---|---|---|---|---|
| | Complete Measurement | | Incomplete Measurement | |
| | Noise free | 3% Noise | Noise free | 3% Noise |
| 1 | -0.19 | 0.98 | 3.57 | 4.95 |
| 2 | 0.17 | 1.88 | -1.19 | -1.54 |
| 3 | 0.01 | -0.45 | -0.15 | 0.79 |
| 4 | -0.01 | -1.96 | 3.68 | -3.21 |
| 5 | -0.02 | -0.56 | -1.06 | 4.99 |
| 6 | -0.04 | 0.64 | 0.52 | 1.19 |
| 7 | -0.05 | 2.51 | -0.05 | 0.27 |
| MAE | 0.07 | 1.28 | 1.46 | 2.42 |
| $\alpha$ | -0.71 | 5.83 | -1.56 | 7.40 |
| $\beta$ | -18.21 | -21.43 | -21.35 | 24.41 |



(a) Global Structure

(b) Sub-structure-Member 4

Fig. 3. Frame Structure

noise at all measured data. The total computational time is 48.5s with complete measurements and the computational time is 27.7s with incomplete measurements. The percentage of mean absolute error in identified values of $EI$ with complete and incomplete measurements is tabulated in Table.I. In this example also the mean absolute error in identified $EI$ values with complete measurements (0.07%) is less than that with incomplete measurement (1.46%) of responses. Similarly the percentage of error in identified damping constants ($\alpha$ and $\beta$) is also more in the case of incomplete measurement (-0.71% and -18.21%) than that of complete measurement case (-1.56% and -21.35%). Hence the DTM derived for beam element is satisfactorily identifying stiffness and damping properties of the beam.

*1) Comparison of results with other time domain methods:* Sandesh and Shankar [14] identified stiffness parameters of a substructure in a similar cantilever with six elements using a time domain Least Square technique with damping included with mean absolute error of 4.51% at 3% noise level which requires measurement at all DOF including rotation. Whereas the DTM algorithm identified results with mean absolute error of 2.42% at 3% noise level with only four translational response measurement and only one angular response measurement. This shows that the DTM algorithm performs well when compared to other SI algorithms.

### *B. Example-2: Sub-structural Identification of frame structure*

A frame steel structure made of nine members is fixed at two supports as shown in Fig.3(a) and it has taken from [15]. Each member has a cross section of 12 × 6mm and a flexural rigidity ($EI$) of 43.2 N.m$^2$. The first natural frequency is 11.9 Hz. The damping effect is taken into account by adopting Rayleigh damping with the modal damping ratio of 5%. The damping constants $\alpha$ and $\beta$ are calculated as 3.919 and 6.36×10$^{-4}$. It is proposed to identify the properties of the top horizontal member 4, which has a length of 1m. The properties of substructure to be identified is indicated by box in Fig.3(a). which has a length of 0.875 m. It is divided into seven elements as shown in Fig.3(b). The structure is excited by a sinusoidal input force of $10sin(2\pi 10t)$ N at the midpoint of the member 6. Since the boundary conditions are unknown, it is necessary to measure translational and angular responses, shear force and bending moment responses of any arbitrary node to define initial state vector. The first two responses can be measured directly by accelerometers and last two responses have to be measured by strain gauges. The initial state vector is formed at the node 8 which is $\{X_8\} = \{y_8(t), \theta_8(t), M_8(t), V_8(t)\}^T$. Since the external excitation force is not applied on the substructure, it is not necessary to measure.

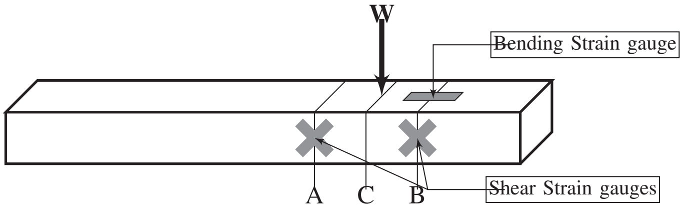


Fig. 4. Strain gauge arrangements

*1) Measurement of shear force and bending moment responses:* For a rectangular section beam, the bending moment response is given by

$$M(t) = \frac{2EI\epsilon_B(t)}{h} \tag{9}$$

The shear force in the section is given by

$$V(t) = \frac{4EI\epsilon_S(t)}{h^2(1+\nu)} \tag{10}$$

where $EI$ is flexural rigidity of the section and $y = h/2$, $h$ is thickness of the section, $\nu$ is Poisson's ratio. The bending strain response can be measured using strain gauge, From the above formulae, to calculate the bending moment and shear force responses at a node, the knowledge of the flexural rigidity ($EI$) at that node is required. The estimation of the $EI$ value at the starting node using a simple shear strain test as is presented here. The strain gauges are fixed to measure bending and shear strain as shown in Fig.4. At a point C in between the nodes A and B, a static load of $W$=10 kN is applied and the corresponding strain at the nodes A and B are measured. Let the static strain measured at the nodes A and B be $\epsilon_{SA}$ and $\epsilon_{SB}$ respectively. The change in shear force at the nodes A and B is equal to the applied load $W$ at C since the self weight of the portion AB is very small. The $EI$ at the initial node B is given by

$$EI = \frac{Wh^2(1+\nu)}{4(\epsilon_{SA} - \epsilon_{SB})} \tag{11}$$

for the measured values $\epsilon_{SA}$=9.8571 × 10$^{-5}$, $\epsilon_{SB}$=-0.0013, $\nu$=0.37 and $h$=6 mm, the $EI$ at the node 8 is obtained as $EI_8$=43.2 N.m$^2$. The bending strain gauges and shear strain gauges fixed at only B are further required for the dynamic strain measurement. The bending moment and shear force responses at the initial node 8 is calculated from measured strain responses using Eq.(9) and Eq.(10).

*2) Parameter Identification:* The initial state vector is formed at the node 8. In case of complete measurement, translational responses are measured at all eight nodes and angular response is measured at initial node only. The parameters were identified by PSO with parameters of swarm size 50 and 50 iterations in each cycle. The total time of identification for seven EI values with complete measurement was 43.84s. The same example is identified with incomplete measurements also. Translational displacement measurements at nodes 1, 3, 5 and 8 are used here. The structure is divided into three portions between nodes (1-3), (3-5) and (5-8). The SI algorithm starts from the initial state vector at the node 8 and identifies parameters of each portion successively. PSO used a swarm size of 50 and 100 iterations in each cycle. The total computational time for convergence was 40.98s. The percentage of error variation in identification of parameters is shown in Table.II. The mean absolute error in identified results of EI is 1.01% with complete measurements and is 4.07% with only four sensors. The DTM performs satisfactorily at 3% Noise level at all measured responses. Also the damping constants are identified with maximum percentage error of -12.84% at incomplete noisy measurement. The input force response is not needed for computation and no need to measure the same. The main advantage of the transfer matrix method is that it is more suitable for the identification of local parameters of complex structure without analysing the entire structure.

TABLE II
PERCENTAGE OF ERROR IN IDENTIFIED RESULTS OF SUBSTRUCTURE OF FRAME

| Element | % of Error | | | |
|---|---|---|---|---|
| | Complete Measurement | | Incomplete Measurement | |
| | Noise free | 3% Noise | Noise free | 3% Noise |
| 1 | 1.34 | -1.40 | 4.99 | 9.99 |
| 2 | 0.29 | 2.99 | -1.84 | -7.71 |
| 3 | 0.96 | 0.05 | 5.02 | 4.99 |
| 4 | -0.16 | -0.33 | 4.11 | -4.38 |
| 5 | -0.41 | 1.53 | -4.54 | -3.26 |
| 6 | -0.14 | -0.74 | -0.58 | -1.84 |
| 7 | -0.01 | -0.04 | 0.23 | 0.74 |
| MAE | 0.47 | 1.01 | 3.05 | 4.07 |
| $\alpha$ | -1.84 | -6.97 | -3.18 | -9.45 |
| $\beta$ | -5.56 | -7.14 | 9.98 | -12.84 |

*3) Comparison of results with other Time domain methods:* It may be noted that Prashanth and Shankar [15] had identified this problem with a 2 stage neural network trained with time domain acceleration signals at two nodes. The error of identification there is expressed as a non-dimensional damage index based on the change in modulus of elasticity of an element. The mean error incurred in that method. was about 0.99% for non-noisy signal and 2.1% for signal with 5% noise but the computational effort of training the network and the complexity of using a two stage network has to be contrasted with the simplicity of the DTM method.

## V. EXPERIMENTAL VERIFICATION OF SUB-STRUCTURE OF A FIXED BEAM

A beam made of acrylic material with cross sectional dimension of 25 ×12 mm and length of 660 mm was fixed at both ends as shown in Fig 5. The modulus of Elasticity ($E$) and density were estimated as 3.7GPa and 1190kg/m$^3$ respectively by simple experiments. The actual flexural rigidity ($EI$) of the beam is 13.32 N.m$^2$. The damping ratio($\zeta$) was calculated from a simple free vibration decay test and estimated as 7%. The natural frequencies for the first two modes are 49.04Hz and 135.45Hz. Assuming Rayleigh's damping model, the exact values of damping constants $\alpha$ and $\beta$ were calculated as 31.67 and 1.21×10$^{-4}$ respectively. The beam was divided into seven elements. A substructure of length 320mm, is shown inside the dotted rectangle in Fig.5 was considered for structural identification. The sub-structure has four elements of length 80 mm each. The node 6 was taken as starting node and the $EI$ value at that node is required to form state vector at node 6. The flexural rigidity ($EI_6$) at the starting node was identified by conducting a static experiment as explained in the section IV-B1. A static load of W=5.045kgf (49.49N) was applied at a point C in between nodes 5 and 6 at a distance 20 mm from the node 6. Strain gauges were fixed as shown in Fig 4. Five sets of readings were taken and the mean values of the shear strains at the points A and B are $\epsilon_{SA} = 9.625\mu$ strain and $\epsilon_{SB} = -170\mu$ strain respectively. The Poisson's ratio ($\nu$) of the beam material is 0.37. Substituting the values in the Eq.(11), the flexural rigidity at the starting node $EI_6$ was obtained which is 13.48 N.m$^2$.

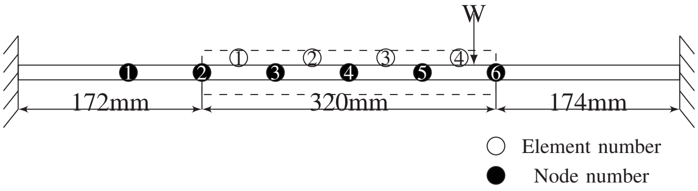

Fig. 5. Substructure of fixed beam

To measure dynamic response, one DYTRAN miniature accelerometer of 2gm mass with sensitivity of 107 mV/g and acceleration range of 50g was fixed at each node to measure translational acceleration. Two accelerometers were fixed very close to each other at a distance of $dx$=7 mm at the starting node 6. The experimental set up is shown in Fig.6. The structure is excited by a sinusoidal force of $3.4sin(2\pi 80t)$ N at the node 1 by a LDS permanent magnet 20 N modal shaker with a maximum displacement of 5 mm with an operating frequency range of 5 Hz-13 kHz. The measurement of input force was not required for this problem, since it was applied outside of the substructure. The strain and acceleration responses were acquired by 16 channel DEWE 1201 data acquisition card(DAC) at a sampling frequency of 1000 Hz. The angular acceleration at the starting node 6 ($\alpha_6$) was calculated by central difference formula. The translational acceleration at the starting node is the mean value of acceleration measured by two accelerometers. Both translational and angular accelerations were converted into respective displacement responses.

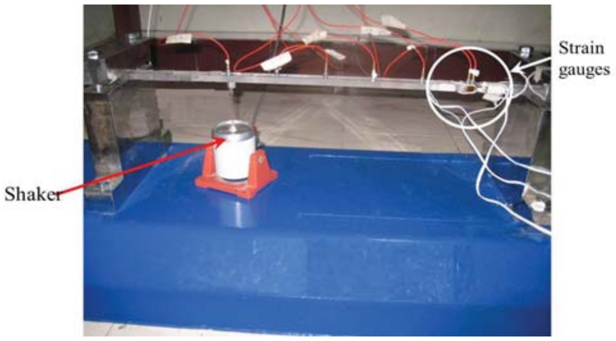

Fig. 6. Experimental set up of Fixed beam

The bending moment and shear force responses at the starting node 6 were calculated from the measured bending and shear strain responses using Eq.(9) and Eq.(10) and state vector at the node 6 was formed. The responses at the other nodes were determined from the starting state vector using DTM with predicted values of structural parameters by PSO. The mean square error between the measured and predicted values of responses were minimized using the Eq.(8). Since there are uncertainty in the experimental data, the parameters were searched between 50% and 200% of their exact value by PSO using damped transfer matrix. The PSO parameters are 50 swarm size, 100 iterations for each identification cycle. The identified parameters are shown in the Table.III. The total computational time taken for convergence is 80.4s. The farthest element 1 was identified with least accuracy, since the error in each identification cycle is accumulated in the state vectors of the succeeding nodes. The DTM algorithm identified the damping properties of the beam with 24.7% and 13.5% mean absolute error. Hence it is clear that the DTM algorithm works on any sub-structure without considering the global model of the complete structure and identifies its local parameters with good accuracy.

TABLE III
IDENTIFIED PARAMETERS OF SUB-STRUCTURE OF FIXED BEAM

| Parameter | Exact | Identified | % of Error |
|---|---|---|---|
| | N.m$^2$ | N.m$^2$ | |
| $EI_1$ | 13.32 | 11.05 | -17.04 |
| $EI_2$ | 13.32 | 12.90 | -3.16 |
| $EI_3$ | 13.32 | 14.43 | 8.39 |
| $EI_4$ | 13.32 | 12.33 | -7.42 |
| $\alpha$ | 31.67 | 39.49 | 24.7 |
| $\beta$ | $1.21 \times 10^{-4}$ | $1.37 \times 10^{-4}$ | 13.50 |

## VI. CONCLUSION

A new SI method based on damped transfer matrix is presented here. The initial state vector has to be provided, and displacement at any point in the structure is predicted using transfer matrix which contains all the structural properties. Using PSO algorithm, the mean square error between measured and predicted responses can be minimized with the unknown structural parameters as the optimization variables. Since the size of the transfer matrix does not increase whatever be the model size, computational effort is reduced. However successive operations are required to identify the unknown parameters. The successive identification method of this algorithm works fast and identifies the structural parameters with good accuracy. Numerical and experimental studies have been made on both global structures with known boundary conditions and sub-structures of unknown boundary conditions. Since the responses measured in the experimental study contains realistic noise and errors, the results have less accuracy when compared with numerically simulated study with artificially added noise. The accuracy of the method is good compared to existing time domain SI methods. A main advantage of this algorithm is the local identification of parameters of structures without the need to model the entire global structure.

# Model-based Fault Detection and Isolation for Wind Turbine

Abdulhamed Hwas* and Reza Katebi**

*PhD student at University of Strathclyde, Glasgow, UK, email: Abdulhamed.hwas@eee.strath.ac.uk

** Industrial Control Centre, University of Strathclyde, Glasgow, UK, email: r.katebi@eee.strath.ac.uk

***Abstract*—** In this paper, a quantitative model based method is proposed for early fault detection and diagnosis of wind turbines. The method is based on designing an observer using a model of the system. The observer innovation signal is monitored to detect faults. For application to the wind turbines, a first principles nonlinear model with pitch angle and torque controllers is developed for simulation and then a simplified state space version of the model is derived for design. The fault detection system is designed and optimized to be most sensitive to system faults and least sensitive to system disturbances and noises. A multi-objective optimization method is then employed to solve this dual problem. Simulation results are presented to demonstrate the performance of the proposed method.

***Keywords***- *fault detection; observer; wind turbine; sensor monitoring*

## I. Introduction

Faulty components in wind turbine can cause high loses in energy production and possible damage to the wind turbines. The losses may be higher for offshore wind farms. This decreases the reliability and increases the cost of maintenance of the wind turbines. Figure 1 shows the percentage breakdown of the number of failures that occurred during the years 2000-2004 [1]. Most failures were linked to the electrical system followed by sensors and blades/pitch components.

Wind turbine fault monitoring that is a means to avoid abnormal event progression and reduces productivity loss, system breakdowns and damage. It increases safety and reliability of the system to achieve higher performance.

Fault diagnosis methods surveyed in literature can be classified into two general categories, quantitative and qualitative methods. In quantitative method, the understanding is expressed in terms of mathematical functional relationships between the inputs and outputs of the system in the form of system descriptions. In qualitative method, the relationships are expressed in terms of qualitative functions between different components of the system. This approach usually depends upon the knowledge from experts in both the normal and fault cases.

This paper proposes an observer-based Fault Detection and Isolation (FDI) method using a multi-objective optimisation procedure. The paper is organized as follows: Next section is concerned with the requirements for designing an observer and theoretical residual generation. Linear state space model of the wind turbine is presented in section III. Multi-objective optimization genetic algorithm is briefly described in section IV. Fault modelling, observer-based FDI and simulation results are demonstrated in section V. Finally, the conclusion is drawn in section VI.

## II. Observer Based Fault Detection

### A. *Observer Design*

The system described by equation (1) is used to design an observer. The mathematical description of the observer is the same as the system except that the observer has an additional term, the gain K(t), which is continuously correcting the system output and improves the state estimates. The observer is defined in equations (2).

$$\begin{aligned}\dot{x}(t)&=Ax(t)+Bu(t)\\ y(t)&=Cx(t)+Du(t)\end{aligned}\tag{1}$$

$$\begin{aligned}\dot{\hat{x}}(t)&=A\hat{x}(t)+Bu(t)+K(t)[y(t)-\hat{y}(t)]\\ \hat{y}(t)&=C\hat{x}(t)+Du(t)\end{aligned}\tag{2}$$

where x, u, y are the state, input and output of the system of dimension n, m and r and A, B, C and D are system matrices of appropriate dimensions. Define the difference between $x(t)$ and $\hat{x}(t)$ as the state error vector (residual), e(t), thus the dynamic error can be written as:

$$\dot{e}=\dot{x}(t)-\dot{\hat{x}}(t)=(A-KC)e(t)\tag{3}$$

For fault monitroing purposes, a weighted residual is defined as follows:

$$r(t)=QCe(t) \tag{4}$$

where Q is residual weighting matrix.

Equation (3) illustrates the dynamic behaviour of the innovation siganl and this is governed by the eigenvalues of the matrix (*A-KC)*. If the matrix A-KC is stable, the error will tend to zero or a constant. If the eigenvalues are chosen in such a way that the dynamic behaviour of the error is asymptotically stable and adequately fast, then any error will tend to zero with sufficient speed. This is possible by choosing an appropriate value for K to achieve the stability, when the system is completely observable [2].

### *B. Residual Generations*

Assume the system is fully observable. The system dynamics with faults and disturbance modelscan be written as:

$$\begin{aligned} \dot{x}(t)&=Ax(t)+Bu(t)+R_1 f(t)+d(t) \\ y(t)&=Cx(t)+Du(t)+R_2 f(t) \end{aligned} \tag{5}$$

where *f(t)* represents the fault vector and considered to be an unknown function of time. The vector *d(t)* is the disturbance vector. The matrices $R_1$ and $R_2$ are the fault distribution matrices.

Using equation (2) and (5), the estimation error and the residual can be written as:

$$\dot{e}=(A-KC)e(t)+d(t)+R_1 f(t)-KR_2 f(t) \tag{6}$$

$$r(t)=Q\ [Ce(t)+R_2 f(t)] \tag{7}$$

Taking Laplace transform of Equation (7) gives:

$$\begin{aligned} r(s)&=Q[R_2+C(sI-A+KC)^{-1}(R_1-KR_2)]\mathrm{f(s)} \\ &+QC(sI-A+KC)^{-1}[d(s)+e(0)] \\ &=G_{rf}(s,K,Q)f(s)+G_{rd}(s,K,Q)[\mathrm{d(s)+e(0)}] \end{aligned} \tag{8}$$

where e(0) is the initial value of the state estimation error.

The effect of the faults on the signal r(t) can be maximized using the following performance index in frequency domain [3]:

$$\begin{aligned} J_f(K,Q)= \sup_{\omega\in[\omega_1,\omega_2]} \bar{\sigma}\{[QR_2+QC(j\omega I-A \\ +KC)^{-1}(R_1-KR_2)]^{-1}\} \end{aligned} \tag{9}$$

where $\bar{\sigma}\{.\}$ denotes the maximal singular value.

The disturbance effects on the residual can be minimised using the following performance index:

$$J_d(K)=\|(A-KC)^{-1}\| \tag{10}$$

Sensor, actuator and component fault matrices can be represented as:

$$\begin{aligned} R_1&=\left|\begin{array}{l|l} 0 & senseor\ fault \\ B & actuator\ fault \\ I & component\ fault \end{array}\right. \\ R_2&=\left|\begin{array}{l|l} I & senseor\ fault \\ D & actuator\ fault \\ 0 & component\ fault \end{array}\right. \end{aligned} \tag{11}$$

Thus we can rewrite fault indices

$$\begin{aligned} J_{af}(K,Q)= \sup_{\omega\in[\omega_1,\omega_2]} \bar{\sigma}\{-[Q_2D+QC(j\omega I \\ -A+KC)^{-1}(B-KD)]\ \} \end{aligned} \tag{12}$$

$$\begin{aligned} J_{sf}(K,Q)= \sup_{\omega\in[\omega_1,\omega_2]} \bar{\sigma}\{[QI+QC(j\omega I-A \\ +KC)^{-1}(-KI)]^{-1}\} \end{aligned} \tag{13}$$

$$\begin{aligned} J_{cf}(K,Q)= \sup_{\omega\in[\omega_1,\omega_2]} \bar{\sigma}\{-[QC(j\omega I-A \\ +KC)^{-1})]\} \end{aligned} \tag{14}$$

The problem can now be stated as minimising the criteria in (12), (13) and (14) subject to the system dynamics in (5). This is a multi-objective optimisation problem and hence genetic algorithm is proposed to solve the problem.

## III. State Space Model of the wind turbine

Mathematical models for the main components of nonlinear 5MW wind turbine system, particularly aerodynamic, two-mass drive train, DFIG generator and their controllers are developed and validated in previous work [4]. The linear state space matrices for a 5 MW wind turbine defined at wind speed 10 m/s is are follows :

Table I description of parameters of the wind turbine [4]

| DESCRIPTION | SYMBOL | DESCRIPTION | SYMBOL |
|---|---|---|---|
| *Turbine inertia* | $J_T$ | *Leakage coefficient* | $\sigma$ |
| *Gearbox ratio* | $n_g$ | *Stator current* | $i_d$, $i_q$ |
| *Generator inertia* | $J_G$ | *Pitch angle* | $\beta$ |
| *Torsional stiffness* | $K_s$ | *Desired pitch angle* | $\beta_d$ |
| *Torsional damping* | $C_s$ | *Mechanical torque* | $T_{wt}$ |
| *Synchronous speed* | $\omega_s$ | *Electrical torque* | $T_e$ |
| *Stator resistance* | $R_s$ | *Control torque* | $T_e^c$ |
| *Rotor resistance* | $R_r$ | *Control rotor voltages* | $v_{dr}$,$v_{qr}$ |
| *Stator inductance* | $L_s$ | *Wind turbine speed* | $\omega_{wt}$ |
| *Rotor inductance* | $L_s$ | *Generator speed* | $\omega_m$ |
| *Mutual inductance* | *Lm* | *Stator voltage* | $v_s$ |
|  |  | *Gearbox ratio* | $n_g$ |

$$A=\begin{bmatrix} -1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & \frac{-1}{n_g} & 0 & 0 \\ 0 & -\frac{K_S}{J_T} & \frac{-C_S}{J_T} & \frac{C_S}{J_T n_g} & 0 & 0 \\ 0 & \frac{K_S}{J_G n_g} & \frac{C_S}{J_G n_g} & \frac{-C_S}{J_G n_g^2} & 0 & 0 \\ 0 & 0 & 0 & -i_q & \frac{-R_S}{\sigma Lr} & (\omega_S-\omega_m) \\ 0 & 0 & 0 & \frac{i_d+L_m u_{sq}}{L_s \omega_s} & -(\omega_S-\omega_m) & \frac{-R_r}{\sigma L_r} \end{bmatrix} \quad (15)$$

$$B=\begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & \frac{1}{J_T} & 0 & 0 & 0 \\ 0 & 0 & \frac{-1}{J_G} & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} \quad (16)$$

$$C=\begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & \frac{-\sqrt{3} n_p L_m V_s K_c}{\sigma L_r L_s \omega_s} \end{bmatrix} \quad (17)$$

where $\dot{\theta}=\omega_{wt}-\frac{\omega_m}{n_g}$ and $K_c$=0.8383. D is zeros matrix.

The states x, inputs u and outputs y are defined as:

$$x=[\beta,\theta_K,\omega_{wt},\omega_m,i_{dr},i_{qr}]^T,$$

$$y=[\beta,\omega_{wt},\omega_m,T_e],$$

$$u=[\beta_d,T_{wt},T_e^c,v_{dr},v_{qr}]^T$$

The physical variables and parameters are described in table I.

## IV. Multi-objective Optimization via Multi Objective Genetic Algorithm Approach

Multi Objective Genetic Algorithm (MOGA) is used to minimise the objective functions. It is more suitable than other approaches such as genetic algorithm because an equality constraint is not required to apply with MOGA [5]. The method finds the solution of problems with two or more objectives to be satisfied all together. Often, such objectives are in conflict with each other, and are expressed in different units. Because of their nature, multi-objective optimization problems normally have not one but a set of solutions, which are called Pareto points or pareto optimal solutions [8].

In order to design the observer, MOGA is used to solve the multi-objective optimization problem defined as follows. Here we need to minimise two objective functions Jsf(K,Q) and Jd(K), with *nxm* decision variable. Mathematically, the problem can be written as:

*Define:*

F(X) = [$F_1$(X); $F_2$(X)]

where $F_1$(X)= 1/$J_{sf}$(K,Q) and $F_2$(x)=$J_d$(K), given that max $J_{sf}$(K,Q)= min (1/$J_{sf}$(K,Q) and X={*x1,......, $x_{nxm}$*} is a vector of decision variables.

The problem is to minimise F(X) subject to:

$F_1^j$(X) ≤ 0 and $F_2^k$(X) ≤ 0.

$F_1^j$ (X): *j*th inequality constraint evaluated at X

$F_2^k$(X) : *k*th equality constraint evaluated at X

In the vector function F(x), some of the objectives may be in conflict with others, and some have to be minimized while others are maximized. The constraints define the feasible region X, and any point *x*∈X is a feasible solution. There is rarely a situation in which all F(X) have an optimum in X at a common point. Therefore, in the absence of preference information, solutions to multi-objective problems are compared using the notion of Pareto dominance.

Without loss of generality, in a minimization problem for all objectives, a solution $X_1$ dominates a solution, $X_2$ if the two following conditions are true:

- $X_1$ is no worse than $X_2$ in all objectives, i.e., $f_i(X_1) \leq f_i(X_2)$
- $X_1$ is strictly better than $X_2$ for at least one objective, i.e., $f_i(X_1) < f_i(X_2)$.

Then, a solution is said to be Pareto-optimal if it is not dominated by any other possible solution, as described above. Thus, the Pareto-optimal solutions to a multi-objective optimization problem form the Pareto front or Pareto-optimal set [9].

The performance indices $J_{sf}$(K,Q) and $J_d$(K) are functions in K and Q. Therefore, the parameters set to be designed are the observer gain matrix and residual weighting factor matrix. The matrix K must achieve the stability of the observer and optimisation of the performance indices. Ackermann's formula is used to parameterize the matrix K [2].

$$K=\left[A^n+\alpha_1 A^{n-1}+\alpha_2 A^{n-2}+\cdots+\alpha_{n-1}A+\alpha_n I\right]\begin{bmatrix} C \\ CA \\ \vdots \\ CA^{n-1} \end{bmatrix}\begin{bmatrix} 0 \\ 0 \\ \vdots \\ 1 \end{bmatrix} \quad (18)$$

where desired eigenvalues are defined as:

$$(s-p_1)(s-p_2)\cdots(s-p_n)=s^n+\alpha_1 s^{n-1}+\alpha_2 s^{n-2}+\cdots+\alpha_{n-1}s+\alpha_n$$

To improve the design desired eigenvalues are assigned in predefined regions to meet stability and response requirements as in equations[10]:

$$p_i = L_i + (U_i - L_i)\sin^2(x_i),\ i=1,...,n$$

$L_i \leq p_i \leq U_i$

where

$U_i$=[-6 -10 -1 -3 -8.5 -14]; $L_i$=[-8 -12 -2 -4 -9.5 -20];

where $U_i$ and $L_i$ are the lower and higher limits for the eigenvalues respectively. Index $x_i$ can be freely selected. Constrained performance indices have now been transformed into unconstrained as a function of X, where K($x_1$, $x_2$, $x_3$, $x_4$, $x_5$, $x_6$) and Q=[$x_7$ $x_{11}$ $x_{15}$ $x_{19}$; $x_8$ $x_{12}$ $x_{16}$ $x_{20}$; $x_9$ $x_{13}$ $x_{17}$ $x_{21}$; $x_{10}$ $x_{14}$ $x_{18}$ $x_{22}$].

The Matlab Genetic Algorithm Toolbox was utilised. The tuning parameters were set as follows: Initial range of variables= [0; 10000], population size: 75, number of generations: 200.

MOGA solver can accept one or more plot functions through the options argument. This feature is useful for visualizing the performance of the solver at run time. Figure 2(b) is the Pareto front, which plots the Pareto front at every generation. Figure 2(a) is the score diversity for each objective.

From Figure 2, there is only one optimal value on the Pareto front figure, that gives J$_{sf}$(K,Q)=infinity and J$_d$(K) = 258. The eigenvalues at these indices P and matrix K, residual weighting factor matrix Q are:

$$K=\begin{bmatrix} 0.012 & -7.6e\text{-}06 & 3.7e\text{-}08 & 7.3e\text{-}10 \\ 0.0001 & -2. & -0.017 & -1.8e\text{-}14 \\ -0.0003 & 15.26 & -0.016 & 3.6e\text{-}14 \\ 0.182 & -4338.1 & 17.35 & -2.2e\text{-}11 \\ -2.2e\text{-}09 & 1.2e\text{-}15 & -672 & -0.40 \\ -2.2e\text{-}09 & 1.4e\text{-}15 & 11.03 & -7.32 \end{bmatrix}$$

$$Q=\begin{bmatrix} 4426 & 4495 & 7814 & 5446 \\ 3015 & 4094 & 6897 & 1503 \\ 3836 & 3872 & 4308 & 8549 \\ 5144 & 6240 & 6211 & 5673 \end{bmatrix}$$

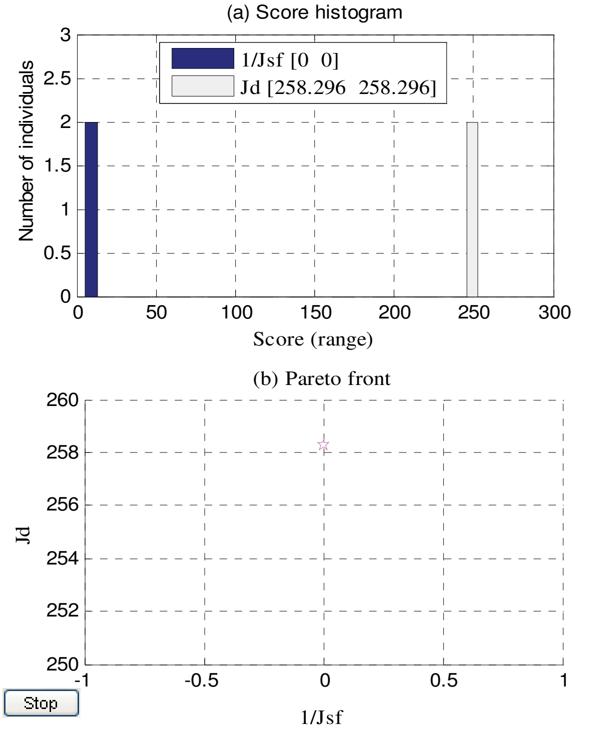

Fig. 2 Pareto front and the number of individuals for sensor and disturbance performances indices.

## V. Observer-based sensor FDI scheme

A successful FDI should be accompanied by a fault isolation procedure to isolate a particular fault from others. For example, to determine in which sensor, actuator or component the fault happened. Observer-based residual generator approach is suitable for detecting a fault [6], but to isolate the fault, a method is proposed here as follows..

### A. Fault Model

Faults are modelled as unknown change in signals as an additive fault. This fault can be classified according to their source as an actuator $\Delta u(t)$, sensor $\Delta y(t)$ or component $\Delta u_c(t)$ faults [3]. Figure 3 shows the effect of additive faults on the observed signals of the inputs and outputs. The component faults affect both the true output and the observed output ( $y_o^c$ ). The observed signals for the input and output can be rewritten as below.

$$u_o(t)=u(t)+\Delta u(t)+\delta u(t) \tag{19}$$

$$y_o^c(t)=u_o(t)+\Delta u_c(t)+\delta u_c(t) \tag{20}$$

$$y_o(t)=y_0^c(t)+\Delta y(t)+\delta y(t) \tag{21}$$

where $u_0(t)$, $y_0^c(t)$ and $y_o(t)$ are the actuator, component and sensor outputs respectively.

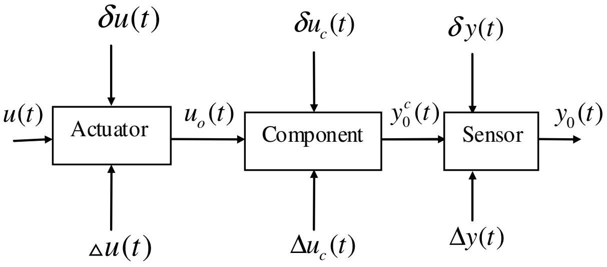

Fig. 3 A diagram for the additive faults, where $\delta u(t)$ and $\delta u_c(t)$ denote the actuator and component disturbance signals respectively. $\delta y(t)$ is a sensor noise signal.

### B. Design of Observer-based Sensor FDI

To design a robust observer-based sensor FDI, we assumed that only one sensor fault occurs, all actuators and components are fault free. Then from equations (5) and (11) the system equation can be expressed as:

$$\begin{aligned} \dot{x}(t)&=Ax(t)+Bu(t)+d(t) \\ y(t)&=Cx(t)+R_2 f(t) \end{aligned} \tag{22}$$

Then the residual generator can be created for each sensor as:

$$r_k(t)=Q[(Ce(t)+R_2 f(t))(C_m-C_k)] \tag{23}$$

where $k$ is the number of the measurement sensor, $C_k$ is obtained from the matrix $C$ by deleting zero columns and assuming $k_{\text{th}}$ row equal zero. $C_m$ is the matrix $C$ without zero columns.

From equation (23), it is obvious that each residual generator is driven making all other residuals equal zero. From above a robust and observer based sensor FDI schemes is designed as shown in figure 4. Each sensor residual ($r_k$) is separated from the output of the residual (r) by $r\ x\,(C_m - C_k)$

, and then dimension of $r_k$ is modified using $Q_k$. The advantage of this approach is that it uses only one observer comparing with other approaches, which use a bank of observers such as a structured residual set designed by a dedicated or a generalized observer scheme [6].

For simulation, the values of the residual weighting factors are selected as follows:

$$\frac{Q_1}{100}=\frac{Q_2}{1000}=Q_3=10\ \ Q_4=Q \qquad (24)$$

Q are then obtained using the Method of Multi Objective Genetic Algorithm. Q1, Q2, Q3 and Q4 are residual weighting factors for pitch angle, rotor speed, generator speed and torque sensors, respectively

### C. Simulation Results

Simulation Results are shown in Figs. 5 to 8. The faults are applied by multiplying the sensor signal by 1.05, i.e. an increase of 5% at 200s, and the transient period is neglected. Fig. 5 shows the residual norm of the pitch sensor increased, when there is a fault. Fig. 6 is for a fault occurred in rotor speed sensor; the residual norm of the rotor and generator rotational speed sensors detects the faults. Fig. 7 for a fault occurred in generator speed sensor and Fig. 8 for a fault occurred in the generator torque sensor. The speed of the fault detection is very fast. Consequently, from figures 5, 6, 7 and 8, we can construct the Boolean decision table as shown in Table II. If a fault occurs, we can compare the results with this fault signature table and decide the location of the fault as shown in the Fig. 4. Therefore, fault detection and isolation are achieved.

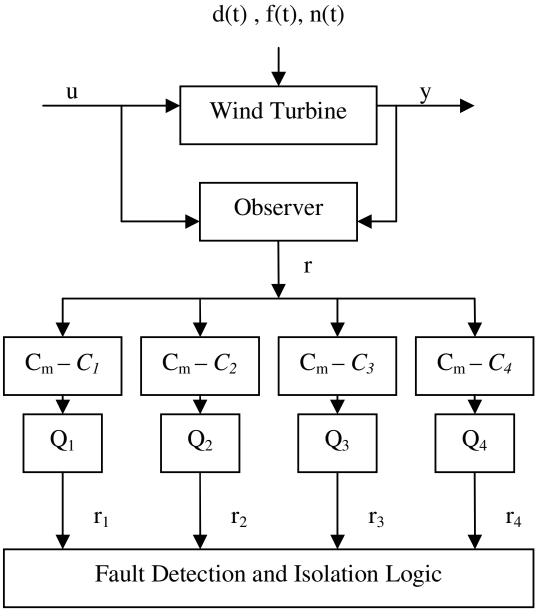

Figure 4 A robust sensor FDI scheme. $r_1$, $r_2$, $r_3$ and $r_4$ represent pitch angle, rotor speed, generator speed and generator torque residuals respectively. r contains residuals for all sensors.

For a specific fault, we can now find its location using the following thresholds:

$$\begin{aligned} r_k(t) &> \mid T_k \mid \Rightarrow f_k(t)=1 \\ r_k(t) &\leq \mid T_k \mid \Rightarrow f_k(t)=0 \end{aligned} \qquad (25)$$

where $T_k$ is the threshold. $f_k(t)$ sensor fault. $k$=1,2 ,3 ,4 (for pitch angle, rotor speed, generator speed and torque sensors).

Table II Boolean decision for sensor faults

| **Residual** | **Pitch residual** | **Rotor speed residual** | **Generator speed residual** | **Electrical torque residual** |
|---|---|---|---|---|
| ***Pitch fault*** | *1* | *0* | *0* | *0* |
| ***Rotor speed fault*** | *0* | *1* | *1* | *0* |
| ***Generator speed fault*** | *0* | *1* | *1* | *1* |
| ***Electrical torque fault*** | *0* | *0* | *0* | *1* |

## VI. Conclusions

A robust observer-based sensor fault detection and isolation scheme is developed for wind turbine. This scheme is systematic and easy to design and implement. Simulation results proved that it is very suitable for detection and isolation faults in sensors and simple to handle multiple faults.

The advantage of the proposed approach is that it depends on only one observer comparing with other approaches, which use a bank of observers such as a structured residual set designed by a dedicated or a generalized observer scheme.

***Abstract*—This paper demonstrates the efficacy of alternative parameterisations of the degrees of freedom within a robust MPC algorithm. Alternative parameterisations have been shown to improve the feasible region when the number of degrees of freedom is limited for the nominal case. This paper extends that work to the robust scenario and shows that similar benefits accrue and moreover, the increase in complexity for the robust case as compared to the nominal case is much less than might be expected. The improvements, with respect to a conventional algorithm, are demonstrated by numerical examples.**

**Keywords: Robust MPC, Alternative parameterisations, Feasibility.**

## I. Introduction

Model Based Predictive Control (MPC) or receding horizon control (RHC) or embedded optimisation or moving horizon or predictive control [1], [2], [3], are general names for different computer control algorithms that use predictions as a basis for forming a control law. MPC has now reached a high level of maturity in academia and is widely used in industry. There is substantial interest in how to develop algorithms for the stochastic case and to deal with nonlinearity or uncertainty, in particular because formal consideration of these issues can lead to substantial computation and/or complexity. The main aim of this paper is to contribute to research which improves feasibility while tackling the robust case, perhaps at some small loss of optimality. Specifically, the focus is on the potential of alternative parameterisations of the degrees of freedom (e.g. [20]) to enable enlargement of feasible regions in the uncertain case without too much detriment to performance, optimality and the computational burden.

Two common approaches to robustness have been considered in MPC literature. The first makes use of the inherent robustness of nominal MPC algorithm design, i.e. MPC algorithm that is not specially designed for robust aspects (like stability and performance) [5], [6]. The second approach is the explicit inclusion of robustness requirements into the design of MPC algorithm and this has received considerable attention in the MPC literature. An MPC algorithm design based on including the uncertainty information in the model will be referred to as robust MPC [7], [8].

Traditionally robust MPC requires the solution of min-max optimisation problem, where optimisation is performed in order to minimize a worst-case cost over all possible uncertainty realisations [9]. Furthermore, this also guaranteed constraint satisfaction for all possible future trajectories. For a min-max optimisation problem, stability was proved in [10] by considering feedback within the horizon. In general, solving a min-max problem subject to constraints has to optimise over a sequence of control strategies rather than a sequence of fixed control moves, as the latter is computationally too demanding for practical implementation [11]. All these aspects contribute to make several variants of robust MPC intractable for on-line optimisation [7], [11].

However, various alternative robust MPC algorithms have been proposed to approximate solutions of the max-min problem but with a reduced computational burden. In [12] a classical result is presented by directly incorporating the plant uncertainty into the MPC formulation. The existence of a feedback law minimising an upper bound on the infinite horizon objective function and satisfying constraints is reduced to a convex optimisation using linear matrix inequalities (LMI). The main disadvantages are the use of LMI-based optimisation that can still be computationally demanding and moreover the methods use conservative constrained handling. Several authors reduced the online computational complexity [11], [13], [14] by performing more offline analysis using invariant ellipsoidal sets, however with a significant restriction to the volume of the feasible region. A robust triple mode MPC algorithm was proposed in [15] by introducing an additional mode in dual mode MPC with a large feasible region and good performance; in essence, the objective is to find suitable and fixed linear time varying (LTV) control law.

Of the numerous robust MPC algorithms, quite a few incorporate the notion of feedback in the prediction sequence over which the on-line optimisations take place as this reduces the divergence of the predictions which occurs in open-loop. This closed-loop paradigm improves the control performance but does not necessarily lead to an inexpensive optimisation strategy [7], [8], [9]. Reduced-complexity invariant sets are introduced in [7] for the case of quasi-infinite horizon closed-loop MPC. The reduced-complexity invariant sets may result in a decrease in the number of on-line optimisation variables [7]. This invariant set structure is used in the design of robust MPC and this paper pursues this type of approach to including uncertainty information in the model ([8], [16]).

In the nominal case, Laguerre, Kautz and generalised parameterisations are able to achieve large feasible regions while

978-1-4673-1560-9/12/$31.00 ©2012 IEEE

maintaining local optimality and a relatively low computational complexity [17], [21], [18], [19], [20]. This paper extends the earlier studies in [18], [20] to the case of parameter uncertainty by developing the algorithm of [7] for constructing polyhedral robust positive invariant sets; this enables the online robust MPC algorithm to be based on a standard quadratic programme while adding the benefits of improved feasibility due to the change in parameterisation.

Section II gives the necessary background about nominal MPC, generalised parameterisations for an optimal MPC and robust MPC. Section III discusses alternative parameterisations within Robust MPC using a generalised parameterisation. An algorithm is proposed for Robust MPC using the generalised parameterisation. Comparisons between the existing Robust MPC (RMPC) and the new proposed algorithms are given in section IV using numerical examples. Finally conclusions and future work are in section V.

## II. Problem formulation for Robust MPC

Assume discrete time linear parameter varying (LPV) state space models of the form [8]

$$\begin{aligned} x_{k+1} = A(k)x_k + B(k)u_k, \\ (A(k),B(k)) \in Co\{[A_1B_1],...,[A_mB_m]\}, \end{aligned} \tag{1}$$

with the nominal model being $(A,B)$ and $x_k \in \mathbb{R}^{n_x}$ and $u_k \in \mathbb{R}^{n_u}$ being the state vectors and the plant input respectively. Assume that the states and inputs at all time instants should fulfill the following constraints:

$$L_x x + L_u u \leq l. \tag{2}$$

### A. Nominal MPC algorithm

The performance index [3], [22] to be minimised, at each sample instant, with respect to $u_k, u_{k+1}, \dots$ is:

$$\begin{aligned} J = \sum_{i=0}^{\infty}(x_{k+i+1})^T Q(x_{k+i+1}) + (u_{k+i})^T R(u_{k+i}) \\ s.t. \left\{ \begin{array}{ll} x_{k+1} = Ax_k + Bu_k, (2) & \forall k \geq 0, \\ u_k = -Kx_k & \forall k \geq n_c, \end{array} \right. \end{aligned} \tag{3}$$

with $Q$ and $R$ positive definite state and input cost weighting matrices and where $K$ is the optimal feedback gain minimizing $J$ in the absence of constraints (2). Practical limitations imply that only a finite number, that is $n_c$, of free control moves can be used [3]. For these cases, $u_k = -Kx_k$ is implemented by ensuring that the state $x_{n_c}$ must be contained in a polytopic control invariant set (often denoted as the maximal admissible set or MAS):

$$\begin{aligned} \chi_0 = \{x_0 \in R^{n_x} : L_x x - L_u K x_k \leq l, \\ x_{k+1} = Ax_k + Bu_k, \forall k \geq 0\}. \end{aligned} \tag{4}$$

For simplicity of notation, the MAS is described in the form $S_0 = \{x : Mx \leq b\}$ for suitable $M$ and $b$ and the d.o.f. can be reformulated in terms of a new variable $c_k$:

$$\begin{aligned} u_k = -Kx_k + c_k, \qquad & k = 0,...,n_c-1, \\ u_k = -Kx_k, \qquad & k \geq n_c. \end{aligned} \tag{5}$$

The MCAS (maximal controlled admissible set) is given as

$$\chi_c = \{x_k : \exists C, Mx_k + NC \leq b\}, \tag{6}$$

where $C = [c_k^T, \dots, c_{k+n_c-1}^T]^T$ and hence the equivalent optimisation to (3) is:

$$\min_C \ J_c = C^T S C \ s.t. \ Mx_k + NC \leq b. \tag{7}$$

The optimal MPC (OMPC) algorithm is given by solving the QP optimisation (7) at every sampling instant then implementing the first component of $C$, that is $c_k$ in the control law of (5). When the unconstrained control law is not predicted to violate constraints (i.e. $x_k \in \chi_0$), the optimising $C$ is zero so the control law is $u_k = -Kx_k$. The optimisation of (7) can require a large $n_c$ d.o.f. to obtain both good performance and a large feasible region.

### B. Generalised parameterisation for Optimal MPC

More recently different alternative parameterisation techniques have been developed to improve the feasible region in nominal case. Laguerre, Kautz and generalised parameterisations have been proposed in [17], [18], [20] as effective alternatives to the standard basis set for parameterising the d.o.f. within an optimal MPC. This section will discuss briefly Laguerre, Kautz and generalised optimal MPC.

The generalised parameterisation [20] is defined using a higher order discrete network such as:

$$\begin{aligned} \mathcal{G}_i(z) = \mathcal{G}_{i-1}(z)\frac{(z^{-1}-a_1)\dots(z^{-1}-a_n)}{(1-a_1z^{-1})\dots(1-a_nz^{-1})}, \\ 0 \leq a_k < 1, \qquad k = 1\dots n. \end{aligned} \tag{8}$$

With $\mathcal{G}_1(z) = \frac{\sqrt{(1-a_1^2)\dots(1-a_n^2)}}{(1-a_1z^{-1})\dots(1-a_nz^{-1})}$. The generalised function with $a_k, \forall k = 1,\dots,n$ gives [20]

$$\begin{aligned} Laguerre\ network: \qquad & \mathcal{G}_i = \mathcal{L}_i, \quad if \ \ a_k = [a]. \\ Kautz\ network: \qquad & \mathcal{G}_i = \mathcal{K}_i, \quad if \ \ a_k = [a,b]. \end{aligned} \tag{9}$$

The generalised sequence can be computed using the following state-space model (this example is 3rd order):

$$\mathcal{G}_{k+1} = \underbrace{\begin{bmatrix} b & 0 & 0 & \dots \\ b & c & 0 & \dots \\ -ab & (1-ac) & a & \dots \\ ab^2 & -b(1-ac) & (1-ac) & \dots \\ \vdots & \vdots & \vdots & \ddots \end{bmatrix}}_{A_G} \mathcal{G}_k, \tag{10}$$

$$\begin{aligned} \mathcal{G}(0) = \gamma[1,1,1,-a,ab,-abc,a^2bc,\dots]^T, \\ \gamma = \sqrt{(1-a^2)(1-b^2)(1-c^2)}. \end{aligned}$$

The prediction using d.o.f. and generalised functions [20] are given by

$$C = \begin{pmatrix} c_k \\ c_{k+1} \\ \vdots \end{pmatrix} = \begin{pmatrix} \mathcal{G}(0)^T \\ \mathcal{G}(1)^T \\ \vdots \end{pmatrix} \rho = H_G \rho, \tag{11}$$

where $\rho$ is the $n_G$ dimension decision variable when one uses the first $n_G$ column of $H_G$. The only difference between Laguerre OMPC and Kautz or generalised OMPC is that of $H_G$ matrix. For further details readers are referred to [18] and [20].

*Algorithm 2.1:* GOMPC

$$\rho^* = arg\ \min_{\rho}\ J_G = \rho^T[\sum_{i=0}^{\infty} A_G^i \mathcal{G}(0) S \mathcal{G}(0)^T (A_G^i)^T]\rho$$
$$s.t.\ Mx_k + NH_G\ \rho\ \leq\ b. \qquad (12)$$

Define $c_k^* = H_G \rho_k^*$ and implement $u_k = -Kx_k + e_1^T c_k^*$. Where $e_1^T = \begin{bmatrix} I, 0, \dots, 0 \end{bmatrix}$.

*Remark 2.1:* It is straightforward to show, with conventional arguments, that all algorithms (i.e. LOMPC, KOMPC, GOMPC) using terminal constraints within MPC problem formulation provides recursive feasibility and Lyapunov stability.

### *C. Robust MPC (RMPC): Dual mode MPC for LPV case*

The robust MPC algorithm, here denoted RMPC, developed in [8] is very similar to the nominal optimal MPC algorithm in (7), but it is applicable to the LPV system in (1). RMPC is designed to minimise the nominal predicted performance cost subject to robust constraint satisfaction by the whole class of possible predictions.

Define an augmented system model which incorporates the 'd.o.f.' as follows:

$$X_{k+1} = \Psi_i X_k,\ \Psi_i = \begin{bmatrix} \Phi_i & B_i E \\ 0 & I_L \end{bmatrix},\ X_k = \begin{bmatrix} x_k \\ c_k \end{bmatrix}. \qquad (13)$$

with $\Phi_i = A_i - B_i K$, $E = \begin{bmatrix} I, 0, \dots, 0 \end{bmatrix}$ and $I_L$ as shift matrix. The associated constraints (2) are represented as:

$$\alpha X \leq \delta,\ \alpha = \begin{bmatrix} L_x & 0 \\ -L_u K & L_u E \end{bmatrix},\ \delta = l. \qquad (14)$$

RMPC algorithm differs from OMPC only in the inequalities that need to be satisfied. It has been shown [8] that RMPC has recursive feasibility and guaranteed stability, under the mild condition that the uncertainty is small enough to allow such an invariant set to exist for all the different dynamics $\Psi_i$. The robust invariant set MAS for LPV system subject to linear constraints is introduced in [7]. The MAS is calculated using an invariant condition which avoids the combinatorial explosion of the number of constraints. The MAS for robust MPC $\chi_{r_0}$ in [8] is defined in compact form as:

$$\chi_{r_0} = \{x_k : M_r x_k \leq br\}. \qquad (15)$$

The associated MCAS in [8] is defined in compact form as:

$$\chi_r = \{x_k : \exists C, M_r x_k + N_r C \leq br\}. \qquad (16)$$

The key success of RMPC is the definition of inequalities, i.e. $M_r, N_r$ and $b_r$; the precise details of how to compute these matrices are omitted and are available in [8]. The performance cost can be (one can make improvements to this but such discussions are beyond the remit of this paper) based on a nominal performance cost but it in particular is phrased in terms of perturbations $c_k$ to the nominal control law.

For ease of reference, we summarise RMPC below and the reader is referred to [8] for further details.

*Algorithm 2.2:* RMPC
At each sampling instant, solve the following optimisation problem:

$$\min_{C} J = C^T S C\ \ s.t.\ \ M_r x_k + N_r C \leq b_r,$$

where only the first block element of $C$ is implemented in the control law of (5).

## III. Using Alternative parameterisation within RMPC

A fundamental weakness of conventional MPC algorithms is poor feasibility with a small number of d.o.f. to move the initial states into the MAS. This weakness may be overcome by increasing the number of d.o.f., but this compromises the computational burden. However, the alternative parameterisations proposed in [17], [21], [18], [20] for the nominal case should significant feasibility improvements, for the same number of d.o.f.. Therefore, this section seeks to extend the use of alternative parameterisation to the robust case and thus explore whether similar feasibility benefits are possible or likely. This section will show how such parameterisation can be used to form robust invariant sets and thus deployed in appropriate robust MPC algorithm. Examples in the next section are used to demonstrate the impact on feasibility.

### *A. Alternative parameterisation within RMPC*

The alternative parameterisation (i.e. Laguerre, Kautz and generalised functions) may be used to improve the feasible region of RMPC. Robust generalised MPC (RGMPC) is a robust MPC algorithm where the d.o.f. or input perturbations $c_k$ are parameterised using generalised functions. As in the conventional case, the prediction cost can be represented in terms of the perturbations $\rho$ about the nominal control law, hence:

$$J_G = \rho^T \left[\textstyle\sum_{i=0}^{\infty} \mathcal{G}(i) S \mathcal{G}(i)^T\right] \rho, \qquad (17)$$

with $c_{k+i} = \mathcal{G}(i)^T \rho$ and $\mathcal{G}(i) = A_G \mathcal{G}(i-1)$.

From (14), we drive the autonomous formulation using generalised parameterisation as:

$$X_{k+1} = \Psi_i X_k,\ \Psi_i = \begin{bmatrix} \phi_i & B_i \mathcal{G}_0^T \\ 0 & A_G^T \end{bmatrix},\ X_k = \begin{bmatrix} x_k \\ \rho_k \end{bmatrix}. \qquad (18)$$

These dynamics should full fill the constraints (2),

$$\alpha X \leq \delta;\ \alpha = \begin{bmatrix} L_x & 0 \\ -L_u K & L_u \mathcal{G}_0^T \end{bmatrix},\ \delta = l. \qquad (19)$$

Robust constraint handling is represented by an MCAS or $\chi_r$ which is calculated offline with the the methodology of [7], [8], but deploying alternative functions, that is equations (18,19) within the update model; this is illustrated in the following algorithm.

*Algorithm 3.1:* RGMPC Given a LPV system (18) subject to linear constraints (19).

1) Set the initial values for $A_S$ and $b_S$ to

$$A_S := \alpha; \qquad b_S := l. \tag{20}$$

2) Initialise the index $i := 1$.
3) Repeat until $i$ is not strictly larger than number of rows in $A_S$.
    a) Select row $i$ from (20), check whether adding any of the constraints $\alpha_i \Psi_i X \leq l_i$, $j = 1, \ldots, m$ to $A_S, b_S$ would decrease the size of $\chi_r$, by solving the following linear programming (LP) for $j = 1, \ldots, m$

$$\begin{aligned} c_j = \max_X \quad & \alpha_i \Psi_i X - l_i \\ s.t. \quad & A_S X \leq b_S. \end{aligned} \tag{21}$$

If $c_j > 0$, then add the constraint to $A_S, b_S$ as follows:

$$A_S := \begin{bmatrix} A_S \\ \alpha_i \Psi_i \end{bmatrix}; \quad b_S := \begin{bmatrix} b_S \\ l_i \end{bmatrix}. \tag{22}$$

    b) Increment i.
4) End.

After calculating the inequalities for invariant set the following RGMPC algorithm can be defined.

*Algorithm 3.2:* RGMPC
At each sampling instant, solve the following optimisation problem:

$$\min_\rho J_G \quad s.t. \quad A_S X \leq b_S.$$

Define $c_k^* = H_G \rho_k^*$ and implement $u_k = -K x_k + e_1^T c_k^*$.

*Remark 3.1:* Algorithm 3.1 will terminate in finite steps and only adds constraints and never removes constraints. It is clear that the resulting $\chi_r = \{X : A_S X \leq b_S\}$ will satisfies a robust positive invariant set. Algorithm convergence and invariance of the resulting set is proved similarly as in [7]. After terminating, it is recommended to remove any redundant constraints.

*Remark 3.2:* MAS or $\chi_{r_0}$ is calculated using above algorithm with $[x, c] = [x, 0]$ or using algorithm defined in [7].

### B. Order selection of the generalised parameterisation dynamic

In generalised parameterisations with higher order prediction dynamics have more flexibility to improve feasible region with a limited number of d.o.f.. So there is a clear choice of selecting the order of the parameterisation dynamics.

The prediction dynamics for the $3rd$ order parameterisation from (10) (which can easily be extended to $nth$ order) is quite generic with distinct eigenvalues. From the autonomous formulation using generalised parameterisation in (18), to fulfill the algebraic relations the dimension of the $A_G$ in (10) must be the same as $n_c$. Moreover the key observation from the augmented model in (18) is that $dim(A_G) = n_c$ is an upper bound on maximum parameterisation dynamics order.

## IV. Numerical Examples

The section will illustrate the efficacy of the alternative parameterisation within robust MPC algorithm by several numerical examples given next. The aim is to compare two aspects: (i) the size of the feasible regions; (ii) the number of inequalities required to describe the robust MCAS. For the purposes of visualisation, figures are restricted to second order systems for which it is possible to plot regions of attraction. The comparisons are based on 4 systems with $x \in \mathbb{R}^2, x \in \mathbb{R}^3$ and $x \in \mathbb{R}^4$. The alternative parameterisations are based on Laguerre, Kautz and generalised functions with $3rd$ order dynamics.

### A. Example 1

$$\begin{aligned} A_1 &= \begin{bmatrix} 1 & 0.2 \\ 0 & 1 \end{bmatrix}, \ B_1 = \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \\ A_2 &= \begin{bmatrix} 1 & 0.1 \\ 0 & 1 \end{bmatrix}, \ B_2 = \begin{bmatrix} 0 \\ 1.5 \end{bmatrix}, \\ C &= \begin{bmatrix} 1 & 0 \end{bmatrix}, \ Q = C^T C, R = 0.5, \ n_c = 2, \ a = 0.5, \\ (a, b) &= (0.5, 0.58) \ and \ (a, b, c) = (0.65, 0.67, 0.64). \end{aligned} \tag{23}$$

### B. Example 2

$$\begin{aligned} A_1 &= \begin{bmatrix} 0.6 & -0.4 \\ 1 & 1.3 \end{bmatrix}, \ B_1 = \begin{bmatrix} 1 \\ 0 \end{bmatrix}, \\ A_2 &= \begin{bmatrix} 0.7 & -0.5 \\ 1 & 1.4 \end{bmatrix}, \ B_2 = \begin{bmatrix} 1.5 \\ 0 \end{bmatrix}, \\ C &= \begin{bmatrix} 1 & 0 \end{bmatrix}, \ Q = C^T C, R = 0.5, \ n_c = 2, \ a = 0.2, \\ (a, b) &= (0.3, 0.35) \ and \ (a, b, c) = (0.41, 0.42, 0.43). \end{aligned} \tag{24}$$

### C. Example 3

$$\begin{aligned} A_1 &= \begin{bmatrix} 1 & 0.1 & 0.1 \\ 0 & 1 & 0.1 \\ 0 & 0 & 1 \end{bmatrix}, \ B_1 = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}, \\ A_2 &= \begin{bmatrix} 1 & 0.2 & 0.2 \\ 0 & 1 & 0.2 \\ 0 & 0 & 1 \end{bmatrix}, \ B_2 = \begin{bmatrix} 0 \\ 0 \\ 1.5 \end{bmatrix}, \\ C &= \begin{bmatrix} 1 & 1 & 1 \end{bmatrix}, \ Q = C^T C, R = 0.5, \ n_c = 2, \ a = 0.4, \\ (a, b) &= (0.55, 0.58) \ and \ (a, b, c) = (0.4, 0.6, 0.58). \end{aligned} \tag{25}$$

### D. Example 4

$$A_1 = \begin{bmatrix} 1 & 0.1 & 0.1 & 0.1 \\ 0 & 1 & 0.1 & 0.1 \\ 0 & 0 & 1 & 0.1 \\ 0 & 0 & 0 & 1 \end{bmatrix}, \; B_1 = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 1 \end{bmatrix},$$

$$A_2 = \begin{bmatrix} 1 & 0.2 & 0.2 & 0.2 \\ 0 & 1 & 0.2 & 0.2 \\ 0 & 0 & 1 & 0.2 \\ 0 & 0 & 0 & 1 \end{bmatrix}, \; B_2 = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 1.5 \end{bmatrix}, \qquad (26)$$

$$C = \begin{bmatrix} 1 & 1 & 1 & 1 \end{bmatrix}, \; Q = C^TC, R = 0.5, \; n_c = 2, \; a = 0.4, \; (a, b) = (0.5, 0.56) \; and \; (a, b, c) = (0.55, 0.57, 0.6).$$

with constraints

$$-1 \leq u_k \leq 1; \quad -10 \leq x_{i_k} \leq 10; \quad i = 1, \dots, 4. \qquad (27)$$

### E. Feasible region comparisons

The region of attraction for examples 1 and 2 are plotted in figure 1 and 2 respectively. It is clear from both figures that the use of alternative (Laguerre, Kautz and generalised (3rd order)) parameterisation techniques within robust MPC algorithms improve the volume of the feasible region or the volume of the maximum control admissible set (MCAS). Table I shows the volume comparisons for examples 1-4 using RMPC, RLMPC, RKMPC and RGMPC (3rd order) algorithms. Alternative parameterisation improves feasible region and thus, based solely on volume considerations and as expected, alternative parameterisation based algorithms to be preferred in robust scenario.

### F. Number of constraints

For completeness, it is important to compare the number of inequalities required to describe the robust MCAS as the complexity of these set descriptions has an impact on the online computational burden, the more inequalities the higher the computational burden in solving the associated QP optimisation (this paper does not discuss issues linked to the exploitation of structure and efficient QP optimisers). The number of inequalities to define $\chi_r$ is compared with same number of d.o.f. in Table II. The number of inequalities with parameterised based algorithms are slightly more in comparison with RMPC algorithms. It is clear that higher order parameterisation improves feasibility needs more d.o.f. which will compromise the complexity benefits.

### G. Summary

The result shown in Figure 1 and 2, it is clear that RGMPC ($3rd$ order) has a large feasible region as compare with other algorithms, but having $n_c = 3$. This is due to the structure of $3rd$ order prediction dynamics which compromises the computational burden. Moreover for Table I and II, an interesting observation is that RGMPC ($3rd$ order) improves feasible region with higher number of inequalities.

RKMPC improves feasible region with slightly higher inequalities as compare with both RLMPC and RMPC for the same number of d.o.f. (i.e. $n_c = 2$). It is also clear from both Table I and II that GKMPC is a better choice with $n_c = 2$.

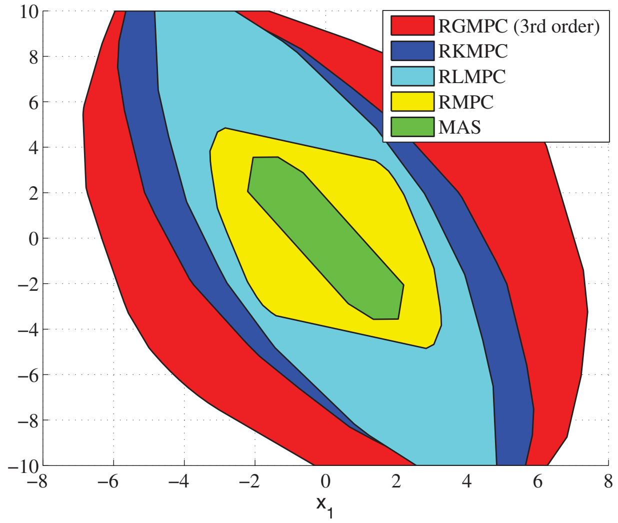

Fig. 1. Feasible regions for model (23) with $n_c = 3$

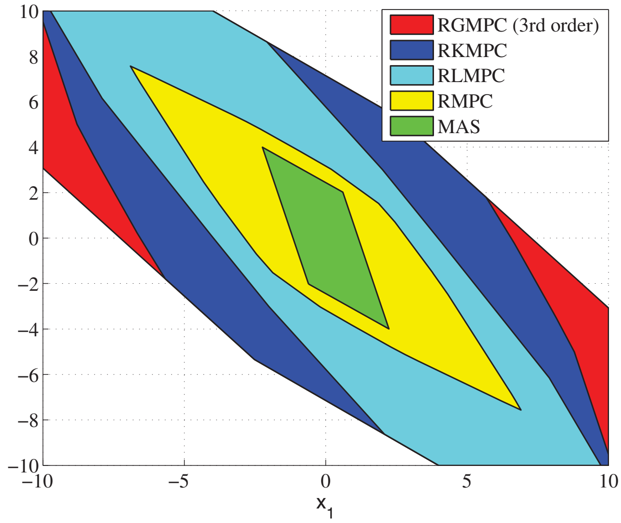

Fig. 2. Feasible regions for model (24) with $n_c = 3$

These results are based on arbitrary choices for the parameters in RGMPC, RKMPC and RLMPC. Further improvements both in feasible region and number of inequalities are possible by tailoring these parameters to the context.

## V. CONCLUSIONS AND FUTURE WORKS

The main contribution of this paper was to extend robust MPC algorithm to make use of alternative parameterisations of the d.o.f. and to consider the impact of doing so. Different alternative parameterisation functions including Laguerre, Kautz and higher order functions can be embedded within the robust MPC approach; the main requirement for this is to

show how a robust invariant set can be computed with different parameterisations of the d.o.f.. Examples based on alternative parameterisation demonstrate that, for a fixed number of d.o.f., in many cases such parameterisations may improve the feasible region without a large change to the number of inequalities required to describe the robust invariant set.

Consequently this approach is worth further investigation. Moreover, there is a need to further investigate in parallel issues such as: which alternative parameterisation is best for particular problem and what choice of parameter(s) within parameterisation will lead to an efficient online optimisation QP structure? From Table II, it is observed that parameter selection effects the number of inequalities. The parameter selection will be based on both number of inequalities and feasible region. Another interesting avenue is to consider the computational efficiency for multi-parameteric quadratic programming (mp-QP) solution to RMPC. Finally, this paper consider parameter uncertainty only and thus extensions to consider disturbances are also required.

*Abstract*—**Polymer flooding is an important technology for enhanced oil recovery (EOR). In this paper, an optimal control model of distributed parameter systems (DPS) for polymer flooding is established, which involves the performance index as maximum of the profit, the governing equations as the seepage equations of polymer flooding, and some inequality constraints as polymer concentration and injection amount limitation. The injection polymer concentration and the terminal time of polymer flooding are chosen as control variables. For this distributed parameter optimal control problem (OCP) with free terminal time, a solution method based on maximum principle is proposed. Firstly, the free terminal time OCP of polymer flooding is transformed into a fixed final time problem by introducing a normalized time variable. Then through application of the maximum principle, adjoint equations and gradients of the objective functional are obtained to optimize the injection polymer concentration and the terminal time simultaneously. Finally, the numerical results of an example illustrate the effectiveness of the proposed method.**

***Keywords-optimal control; maximum principle; distributed parameter system; polymer flooding; free terminal time.***

## I. INTRODUCTION

The optimal control method has been researched in EOR techniques in recent years. Ramirez and Fathi firstly applied it to optimize the injection process of surfactant flooding [1], [2]. Then the optimal control method was used to other enhanced oil recovery techniques [3], such as steam flooding, caustic flooding and gas injection etc. The optimal gas-cycling decision problem of a condensate reservoir has been studied by Ye [4]. The dynamic optimization of water flooding with smart wells has been studied before by Brouwer [5], [6], Sarma [7], [8] and Zhang [9].

Polymer flooding is one of the most effective EOR techniques [10]. Because of the high costs associated with polymer flooding projects, optimal control method must be developed to reduce producing costs while increasing the profit of oil recovered. In this paper, the OCP of a polymer flooding process with free terminal time is considered. The performance index of the OCP is expressed by maximizing the economic benefit. The governing equations are a set of partial differential equations (PDEs), which are a pressure equation, a water saturation equation and a polymer concentration equation respectively. The constraint conditions include the polymer concentration constraint and other inequality constraints. The control variables are chosen as the injection concentrations and the free terminal time. Then the determination of polymer injection strategies turns to solve this OCP of DPS. A normalized time variable is introduced to transform the free terminal time OCP of polymer flooding into a fixed final time problem. Then the necessary conditions for optimality are obtained by Pontryagin's maximum principle. A gradient numerical method is presented for solving the transformed OCP. Finally, an example of polymer flooding project involving a heterogeneous reservoir case is investigated and the results show the efficiency of the proposed method.

The rest of this article is organized as follows: In section II the optimal control model of polymer flooding with free terminal time is built. In section III the original OCP with free terminal time is transformed into a fixed terminal time problem and the necessary conditions for optimality are obtained. In section IV a gradient numerical method is proposed for solving the transformed OCP. In section V an example of polymer flooding accompanied with the optimal results is given. And in section VI some conclusions are derived.

## II. MATHEMATICAL FORMULATION OF OPTIMAL CONTROL

### A. Performance Index

Let $\Omega \in R^2$ denote the domain of reservoir with boundary $\partial\Omega$, $n$ be the unit outward normal on $\partial\Omega$, and $(x,y)\in\Omega$ be the coordinate of a point in the reservoir. We suppose that there exist $N_w$ injection wells and $N_o$ production wells in the oilfield. The injection wells are located at $L_w = \{(x_{wi}, y_{wi}) \mid i = 1,2,\ldots,N_w\}$ and the production wells are located at $L_o = \{(x_{oj}, y_{oj}) \mid j = 1,2,\ldots,N_o\}$, respectively. For polymer flooding, we might wish to increase the profit and reduce the producing cost. Given a free terminal time $t_f$, the performance index is given mathematically by

$$\max\ J = \int_0^{t_f} \iint_\Omega \left[\xi_o(1-f_w)q_{out} - \xi_p q_{in} c_{pin}\right] d\sigma dt, \qquad (1)$$

This work is partially supported by the Natural Science Foundation of China Grant #60974039, the Natural Science Foundation of Shandong Province of China Grant #ZR2011FM002 and the Fundamental Research Funds for the Central Universities Grant #27R1105018A.

where $\xi_p$ is the cost coefficient of polymer ($10^4\$/m^3$), $\xi_o$ is the price coefficient of oil ($10^4\$/m^3$), $f_w$ is the fractional flow of water, $q_{in}$ is the velocity of polymer injection ($m/day$), $q_{out}$ is the velocity of fluid production ($m/day$) and $c_{pin}$ is the injection concentration of polymer ($g/L$).

### *B. Governing Equations*

Let $p(x,y,t)$, $S_w(x,y,t)$ and $c_p(x,y,t)$ denote the pressure, water saturation and polymer concentration of the reservoir, respectively, at a point $(x,y)\in\Omega$ and a time $t\in[0,t_f]$, then $p(x,y,t)$, $S_w(x,y,t)$ and $c_p(x,y,t)$ satisfy the following partial differential equations (PDEs):

- Pressure equation

$$\frac{\partial}{\partial x}\left(k_p r_o\frac{\partial p}{\partial x}\right)+\frac{\partial}{\partial y}\left(k_p r_o\frac{\partial p}{\partial y}\right)-(1-f_w)q_{out}=h\frac{\partial a_o}{\partial t}, \quad (2)$$

- Water saturation equation

$$\frac{\partial}{\partial x}\left(k_p r_w\frac{\partial p}{\partial x}\right)+\frac{\partial}{\partial y}\left(k_p r_w\frac{\partial p}{\partial y}\right)+q_{in}-f_w q_{out}=h\frac{\partial a_w}{\partial t}, \quad (3)$$

- Polymer concentration equation

$$\begin{aligned}&\frac{\partial}{\partial x}\left(k_d r_d\frac{\partial c_p}{\partial x}\right)+\frac{\partial}{\partial x}\left(k_p r_c\frac{\partial p}{\partial x}\right)+\frac{\partial}{\partial y}\left(k_d r_d\frac{\partial c_p}{\partial y}\right)+\\&\frac{\partial}{\partial y}\left(k_p r_c\frac{\partial p}{\partial y}\right)+q_{in}c_{pin}-f_w q_{out}c_p=h\frac{\partial a_c}{\partial t}.\end{aligned} \quad (4)$$

The boundary conditions and initial conditions are

$$\left.\frac{\partial p}{\partial n}\right|_{\partial\Omega}=0,\ \left.\frac{\partial S_w}{\partial n}\right|_{\partial\Omega}=0,\ \left.\frac{\partial c_p}{\partial n}\right|_{\partial\Omega}=0, \quad (5)$$

$$\begin{aligned}&p(x,y,0)=p^0(x,y),\ S_w(x,y,0)=S_w^0(x,y),\\&c_p(x,y,0)=c_p^0(x,y),\end{aligned} \quad (6)$$

The corresponding parameters in (2)–(4) are defined as

$$k_p=Kh\,,\ k_d=Dh\,, \quad (7)$$

$$r_o=\frac{k_{ro}}{B_o\mu_o}\,,\ r_w=\frac{k_{rw}}{B_wR_k\mu_w}\,,\ r_c=\frac{k_{rw}c_p}{B_wR_k\mu_p}\,,\ r_d=\frac{\phi_p S_w}{B_w}, \quad (8)$$

$$a_o=\frac{\phi(1-S_w)}{B_o},\ a_w=\frac{\phi S_w}{B_w},\ a_c=\frac{\phi_p S_w c_p}{B_w}+\rho_r(1-\phi)C_{rp}, \quad (9)$$

where $K(x,y)$ is the absolute permeability ($\mu m^2$), $h$ is the thickness of the reservoir bed ($m$), $D$ is the diffusion coefficient of polymer ($m^2/s$), $\rho_r$ ($kg/m^3$) is the rock density, and $\mu_o$ ($mPa\cdot s$) is the oil viscosity. Other parameters definition can refer to [11] for details.

### *C. Constraints*

The performance index (1) should be subject to the polymer concentration constraint

$$0\le c_{pin}\le c_{\max}, \quad (10)$$

the injection amount constraint

$$\int_0^{t_f}\iint_\Omega q_{in}c_{pin}d\sigma dt\le m_{p\max}, \quad (11)$$

and the terminal state constraint

$$f_w|_{t=t_f}=98\%, \quad (12)$$

where $c_{\max}$ is the maximum injection concentration and $m_{p\max}$ is the maximum polymer amount.

## III. Necessary Conditions of Optimal Control

### *A. Problem Transformation*

For the orginal OCP of polymer flooding with free terminal time, a normalized time variable is introduced,

$$\tau=t/t_f, \quad (13)$$

Since $t\in[0,\ t_f]$, we have $\tau\in[0,\ 1]$. By using the definite integral by substitution, the performance index (1) is expressed as

$$\max\ J=\int_0^1\iint_\Omega t_f\left[\xi_o(1-f_w)q_{out}-\xi_p q_{in}c_{pin}\right]d\sigma d\tau. \quad (14)$$

The system state vector is denoted by

$$\boldsymbol{u}(x,y,t)=[p,S_w,c_p]^T. \quad (15)$$

The control for the process is the polymer concentration of injected fluid

$$v(x,y,t)=c_{pin},\ (x,y)\in L_w. \quad (16)$$

Then the governing equations (2)–(4) which can be expressed by

$$\frac{\partial\boldsymbol{a}}{\partial t}=\tilde{\boldsymbol{f}}(\boldsymbol{u},\boldsymbol{u}_x,\boldsymbol{u}_y,\boldsymbol{u}_{xx},\boldsymbol{u}_{yy},v,t), \quad (17)$$

are normalized as

$$\frac{\partial\boldsymbol{a}}{\partial\tau}=t_f\tilde{\boldsymbol{f}}(\boldsymbol{u},\boldsymbol{u}_x,\boldsymbol{u}_y,\boldsymbol{u}_{xx},\boldsymbol{u}_{yy},v,\tau), \quad (18)$$

where $\boldsymbol{u}_l=\partial\boldsymbol{u}/\partial l$, $l=x,y$.

If $t_f$ is treated as a new optimization variable and $\boldsymbol{v}=[v,\ t_f]^T$ is denoted as control vector, the orginal OCP of polymer flooding is transformed into the following fixed terminal time problem,

$$\max\ J=\int_0^1\iint_\Omega F(\boldsymbol{u},\boldsymbol{v},\tau)d\sigma d\tau, \quad (19)$$

$$s.t.\ \ \boldsymbol{f}(\dot{\boldsymbol{u}},\boldsymbol{u},\boldsymbol{u}_x,\boldsymbol{u}_y,\boldsymbol{u}_{xx},\boldsymbol{u}_{yy},\boldsymbol{v},\tau)=0 \tag{20}$$

$$\boldsymbol{g}(\boldsymbol{u},\boldsymbol{u}_x,\boldsymbol{u}_y,\boldsymbol{u}_{xx},\boldsymbol{u}_{yy},\tau)=0\ , \tag{21}$$

$$\boldsymbol{u}(x,y,0)=\boldsymbol{u}^0(x,y), \tag{22}$$

$$\int_0^1\iint_\Omega c_1(\boldsymbol{v})d\sigma d\tau \le 0, \tag{23}$$

$$c_2(\boldsymbol{u}|_{\tau=1})=0, \tag{24}$$

$$0\le \boldsymbol{v}\le \boldsymbol{v}_{\max}. \tag{25}$$

where $\dot{\boldsymbol{u}}=\partial\boldsymbol{u}/\partial\tau$. With this transformation, at $t=t_f$, $\tau_f=1$, and in the dimensionless time domain the terminal time is fixed.

### *B. Maximum Principle of DPS*

A convenient way to cope with such an OCP of DPS (19)–(25) is through the use of distributed adjoint variables. We define the Hamiltonian as

$$H=F+\boldsymbol{\lambda}^T\boldsymbol{f}, \tag{26}$$

where $\boldsymbol{\lambda}(x,y,\tau)$ is the adjoint vector. Then the argument functional is given by,

$$\begin{aligned} J_A &= J+\int_0^1\iint_\Omega \boldsymbol{\lambda}^T\boldsymbol{f}(\dot{\boldsymbol{u}},\boldsymbol{u},\boldsymbol{u}_x,\boldsymbol{u}_y,\boldsymbol{u}_{xx},\boldsymbol{u}_{yy},\boldsymbol{v},\tau)d\sigma d\tau \\ &= \int_0^1\iint_\Omega H(\dot{\boldsymbol{u}},\boldsymbol{u},\boldsymbol{u}_x,\boldsymbol{u}_y,\boldsymbol{u}_{xx},\boldsymbol{u}_{yy},\boldsymbol{v},\tau)d\sigma d\tau. \end{aligned} \tag{27}$$

The increment of $J_A$, denoted by $\Delta J_A$, is formed by introducing variations $\delta\boldsymbol{u}$, $\delta\boldsymbol{u}_x$, $\delta\boldsymbol{u}_y$, $\delta\boldsymbol{u}_{xx}$, $\delta\boldsymbol{u}_{yy}$, $\delta\dot{\boldsymbol{u}}$, and $\delta v$ giving

$$\begin{aligned}\Delta J_A = {} & J_A(\boldsymbol{u}+\delta\boldsymbol{u},\boldsymbol{u}_x+\delta\boldsymbol{u}_x,\boldsymbol{u}_y+\delta\boldsymbol{u}_y,\boldsymbol{u}_{xx}+\delta\boldsymbol{u}_{xx},\boldsymbol{u}_{yy}+\delta\boldsymbol{u}_{yy}, \\ & \dot{\boldsymbol{u}}+\delta\dot{\boldsymbol{u}},\boldsymbol{v}+\delta\boldsymbol{v})-J_A(\boldsymbol{u},\boldsymbol{u}_x,\boldsymbol{u}_y,\boldsymbol{u}_{xx},\boldsymbol{u}_{yy},\dot{\boldsymbol{u}},\boldsymbol{v}).\end{aligned} \tag{28}$$

Expanding (28) in a Taylor series and retaining only the linear terms gives the variation of the functional, $\delta J_A$,

$$\begin{aligned}\delta J_A = \int_0^1\iint_\Omega\Bigg[ & \left(\frac{\partial H}{\partial\boldsymbol{u}}\right)^T\delta\boldsymbol{u}+\left(\frac{\partial H}{\partial\boldsymbol{u}_x}\right)^T\delta\boldsymbol{u}_x+\left(\frac{\partial H}{\partial\boldsymbol{u}_{xx}}\right)^T\delta\boldsymbol{u}_{xx}+ \\ & \left(\frac{\partial H}{\partial\boldsymbol{u}_y}\right)^T\delta\boldsymbol{u}_y+\left(\frac{\partial H}{\partial\boldsymbol{u}_{yy}}\right)^T\delta\boldsymbol{u}_{yy}+\left(\frac{\partial H}{\partial\dot{\boldsymbol{u}}}\right)^T\delta\dot{\boldsymbol{u}}+ \\ & \left(\frac{\partial H}{\partial\boldsymbol{v}}\right)^T\delta\boldsymbol{v}\Bigg]d\sigma d\tau.\end{aligned} \tag{29}$$

Since the variations $\delta\boldsymbol{u}$, $\delta\boldsymbol{u}_l$, $\delta\boldsymbol{u}_{ll}$ ($l=x,y$) and $\delta\dot{\boldsymbol{u}}$ are not independent can be expressed in terms of the variations $\delta\boldsymbol{u}$ by integrating the following three terms by parts

$$\begin{aligned}\iint_\Omega\left[\left(\frac{\partial H}{\partial\boldsymbol{u}_l}\right)^T\delta\boldsymbol{u}_l\right]d\sigma = {} & \iint_\Omega\frac{\partial}{\partial l}\left[\left(\frac{\partial H}{\partial\boldsymbol{u}_l}\right)^T\delta\boldsymbol{u}\right]d\sigma- \\ & \iint_\Omega\left[\frac{\partial}{\partial l}\left(\frac{\partial H}{\partial\boldsymbol{u}_l}\right)^T\delta\boldsymbol{u}\right]d\sigma,\end{aligned} \tag{30}$$

$$\begin{aligned}\iint_\Omega\left[\left(\frac{\partial H}{\partial\boldsymbol{u}_{ll}}\right)^T\delta\boldsymbol{u}_{ll}\right]d\sigma = {} & \iint_\Omega\left[\frac{\partial^2}{\partial l^2}\left(\frac{\partial H}{\partial\boldsymbol{u}_{ll}}\right)\right]^T\delta\boldsymbol{u}d\sigma+ \\ & \iint_\Omega\frac{\partial}{\partial l}\left[\left(\frac{\partial H}{\partial\boldsymbol{u}_{ll}}\right)^T\delta\boldsymbol{u}_l-\frac{\partial}{\partial l}\left(\frac{\partial H}{\partial\boldsymbol{u}_{ll}}\right)^T\delta\boldsymbol{u}\right]d\sigma,\end{aligned} \tag{31}$$

$$\int_0^1\left(\frac{\partial H}{\partial\dot{\boldsymbol{u}}}\right)^T\delta\dot{\boldsymbol{u}}=\left[\left(\frac{\partial H}{\partial\dot{\boldsymbol{u}}}\right)^T\delta\boldsymbol{u}\right]\Bigg|_0^1-\int_0^1\frac{\partial}{\partial\tau}\left(\frac{\partial H}{\partial\dot{\boldsymbol{u}}}\right)^T\delta\boldsymbol{u}d\tau. \tag{32}$$

By using the above expressions (30)–(32), the first variation $\delta J_A$ is written as

$$\begin{aligned}\delta J_A = {} & \int_0^1\iint_\Omega\left(\frac{\partial H}{\partial\boldsymbol{u}}-\sum_{l=x,y}\frac{\partial}{\partial l}\frac{\partial H}{\partial\boldsymbol{u}_l}+\sum_{l=x,y}\frac{\partial^2}{\partial l^2}\frac{\partial H}{\partial\boldsymbol{u}_{ll}}+\right. \\ & \left.-\frac{\partial}{\partial\tau}\frac{\partial H}{\partial\dot{\boldsymbol{u}}}\right)^T\delta\boldsymbol{u}d\sigma d\tau+\int_0^1\iint_\Omega\sum_{l=x,y}\frac{\partial}{\partial l}\left\{\left(\frac{\partial H}{\partial\boldsymbol{u}_{ll}}\right)^T\delta\boldsymbol{u}_l+\right. \\ & \left.\left[\frac{\partial H}{\partial\boldsymbol{u}_l}-\frac{\partial}{\partial l}\left(\frac{\partial H}{\partial\boldsymbol{u}_{ll}}\right)^T\right]\delta\boldsymbol{u}\right\}d\sigma d\tau+ \\ & \iint_\Omega\left[\left(\frac{\partial H}{\partial\dot{\boldsymbol{u}}}\right)^T\delta\boldsymbol{u}\right]\Bigg|_0^1 d\sigma+\int_0^1\iint_\Omega\left(\frac{\partial H}{\partial\boldsymbol{v}}\right)\delta v d\sigma\, d\tau.\end{aligned} \tag{33}$$

Applying Pontryagin's Maximum Principle, the necessary conditions for an extremum of $J_A$ are given by

- Adjoint Equations

$$\frac{\partial H}{\partial\boldsymbol{u}}-\sum_{l=x,y}\left(\frac{\partial}{\partial l}\frac{\partial H}{\partial\boldsymbol{u}_l}+\frac{\partial^2}{\partial l^2}\frac{\partial H}{\partial\boldsymbol{u}_{ll}}\right)-\frac{\partial}{\partial\tau}\frac{\partial H}{\partial\dot{\boldsymbol{u}}}=0. \tag{34}$$

- Transversality Boundary Conditions

$$\iint_\Omega\sum_{l=x,y}\frac{\partial}{\partial l}\left\{\left(\frac{\partial H}{\partial\boldsymbol{u}_{ll}}\right)^T\delta\boldsymbol{u}_l+\left[\frac{\partial H}{\partial\boldsymbol{u}_l}-\frac{\partial}{\partial l}\left(\frac{\partial H}{\partial\boldsymbol{u}_{ll}}\right)^T\right]\delta\boldsymbol{u}\right\}d\sigma=0. \tag{35}$$

- Transversality Terminal Conditions

$$\frac{\partial H}{\partial\dot{\boldsymbol{u}}}=0\ ,\ \text{ at }\ \tau=1. \tag{36}$$

- Optimal Control

With the first three necessary conditions being satisfied, the first variation becomes

$$\delta J_A = \int_0^1 \iint_\Omega \left( \frac{\partial H}{\partial \boldsymbol{v}} \right) \delta \boldsymbol{v} d\sigma d\tau. \tag{37}$$

If the variation $\boldsymbol{\delta v}$ is not constrained, then the necessary condition for an extremum is $\partial H / \partial \boldsymbol{v} = 0$ .

If the variation $\boldsymbol{\delta v}$ is constrained, which means that the control is at a constraint boundary, then the necessary condition for maximizing the performance functional is

$$\max_{\boldsymbol{v}} H. \tag{38}$$

### C. Necessary Conditions of OCP for Polymer Flooding

Let $\lambda(x,y,\tau) = (\lambda_1, \lambda_2, \lambda_3)^T$ denote the adjoint vector of OCP for polymer flooding. Applying the theory developed and substituting the governing equations (2)–(4) into (34), the adjoint equations reduce for the polymer flooding under consideration as given in,

$$\begin{aligned}&\sum_{l=x,y} \left\{ \frac{\partial}{\partial l} \left( k_p r_o \frac{\partial \lambda_1}{\partial l} \right) + \frac{\partial}{\partial l} \left( k_p r_w \frac{\partial \lambda_2}{\partial l} \right) + \frac{\partial}{\partial l} \left( k_p r_c \frac{\partial \lambda_3}{\partial l} \right) - \right. \\ &\left. \left[ k_p \frac{\partial r_o}{\partial p} \frac{\partial p}{\partial l} \frac{\partial \lambda_1}{\partial l} + k_d \frac{\partial r_w}{\partial p} \frac{\partial p}{\partial l} \frac{\partial \lambda_2}{\partial l} + \left( k_p \frac{\partial r_c}{\partial p} \frac{\partial p}{\partial l} + \right. \right. \right. \\ &\left. \left. \left. k_d \frac{\partial r_d}{\partial p} \frac{\partial c_p}{\partial l} \right) \frac{\partial \lambda_3}{\partial l} \right] \right\} - q_{out} \left( \xi_o \frac{\partial f_w}{\partial p} - \frac{\partial f_w}{\partial p} \lambda_1 + \frac{\partial f_w}{\partial p} \lambda_2 + \right. \\ &\left. c_p \frac{\partial f_w}{\partial p} \lambda_3 \right) + \frac{\partial a_o}{\partial p} \frac{\partial \lambda_1}{\partial \tau} + \frac{\partial a_w}{\partial p} \frac{\partial \lambda_2}{\partial \tau} + \frac{\partial a_c}{\partial p} \frac{\partial \lambda_3}{\partial \tau} = 0,\end{aligned} \tag{39}$$

$$\begin{aligned}&\sum_{l=x,y} \left[ -k_p \frac{\partial p}{\partial l} \left( \frac{\partial r_o}{\partial S_w} \frac{\partial \lambda_1}{\partial l} + \frac{\partial r_w}{\partial S_w} \frac{\partial \lambda_2}{\partial l} + \frac{\partial r_c}{\partial S_w} \frac{\partial \lambda_3}{\partial l} \right) - \right. \\ &\left. k_d \frac{\partial r_d}{\partial S_w} \frac{\partial c_p}{\partial l} \frac{\partial \lambda_3}{\partial l} \right] - q_{out} \left( \xi_o \frac{\partial f_w}{\partial S_w} - \frac{\partial f_w}{\partial S_w} \lambda_1 + \frac{\partial f_w}{\partial S_w} \lambda_2 + \right. \\ &\left. c_p \frac{\partial f_w}{\partial S_w} \lambda_3 \right) + \frac{\partial a_o}{\partial S_w} \frac{\partial \lambda_1}{\partial \tau} + \frac{\partial a_w}{\partial S_w} \frac{\partial \lambda_2}{\partial \tau} + \frac{\partial a_c}{\partial S_w} \frac{\partial \lambda_3}{\partial \tau} = 0,\end{aligned} \tag{40}$$

$$\begin{aligned}&\sum_{l=x,y} \left[ \frac{\partial}{\partial l} \left( k_d r_d \frac{\partial \lambda_3}{\partial l} \right) - k_p \frac{\partial p}{\partial l} \left( \frac{\partial r_w}{\partial c_p} \frac{\partial \lambda_2}{\partial l} + \frac{\partial r_c}{\partial c_p} \frac{\partial \lambda_3}{\partial l} \right) \right] - \\ &q_{out} \left[ \xi_o \frac{\partial f_w}{\partial c_p} - \frac{\partial f_w}{\partial c_p} \lambda_1 + \frac{\partial f_w}{\partial c_p} \lambda_2 + \left( c_p \frac{\partial f_w}{\partial c_p} + f_w \right) \lambda_3 \right] + \\ &\frac{\partial a_c}{\partial c_p} \frac{\partial \lambda_3}{\partial \tau} = 0,\end{aligned} \tag{41}$$

The boundary conditions of adjoint equations for the OCP of polymer flooding are expressed as

$$\left( r_o \frac{\partial \lambda_1}{\partial l} + r_w \frac{\partial \lambda_2}{\partial l} \right) \Bigg|_{\partial \Omega} = 0, \ \frac{\partial \lambda_3}{\partial l} \Bigg|_{\partial \Omega} = 0, \ l = x, y. \tag{42}$$

The terminal conditions of adjoint equations can be simplified to

$$\lambda_1(x,y,\tau_f) = 0, \ \lambda_2(x,y,\tau_f) = 0, \ \lambda_3(x,y,\tau_f) = 0. \tag{43}$$

## IV. Numerical Solution

We propose an iterative numerical technique for determining the optimal injection strategies of polymer flooding. The computational procedure is based on adjusting estimates of control $\boldsymbol{v}$ to improve the value of the objective functional. If the control $\boldsymbol{v}$ is not optimal, then a correction $\boldsymbol{\delta v}$ is determined so that the functional is made lager, that is, $\delta J_A > 0$ . If $\boldsymbol{\delta v}$ is selected as

$$\boldsymbol{\delta v} = w \cdot \frac{\partial H}{\partial \boldsymbol{v}}, \tag{44}$$

where $w$ is an arbitrary positive weighting factor. Then the functional variation becomes

$$\delta J_A = \int_0^1 \iint_\Omega w \left( \frac{\partial H}{\partial \boldsymbol{v}} \right)^T \left( \frac{\partial H}{\partial \boldsymbol{v}} \right) d\sigma d\tau \geq 0. \tag{45}$$

Thus, choosing $\boldsymbol{\delta v}$ as the gradient direction ensures a local improvement in the objective functional, $J_A$ . Substituting the governing equations into (44), we obtain the gradient of performance index with respect to the injection polymer concentration $v$

$$\nabla J(v) = w t_f q_{in} (\lambda_3 - \xi_p), \ (x,y) \in L_w, \tag{46}$$

and the gradient of performance index with respect to the terminal time $t_f$

$$\nabla J(t_f) = w \int_0^1 \iint_\Omega \left[ \xi_o (1 - f_w) q_{out} - \xi_p q_{in} c_{pin} + \boldsymbol{\lambda}^T \tilde{\boldsymbol{f}} \right] d\sigma d\tau, \tag{47}$$

The computational algorithm of control iteration based on gradient direction is as follows:

(1) Initialization: Make an initial guess for the control $t_f$ and $v(x,y,\tau)$ , $(x,y) \in L_w$ , $\tau \in [0, 1]$ .

(2) Resolution of Governing Equations: Using stored current value of control, integrate the governing equations forward in time with known initial governing conditions. The profit functional is evaluated, and the coefficients involved in the adjoint equations which are function of the state solution are computed and stored.

(3) Resolution of Adjoint Equations: Using the stored coefficients, integrate the adjoint equations numerically backward in time with known final time adjoint conditions by Equation (43). Compute and store $\nabla J(\boldsymbol{v})$ as defined by Equations (46) and (47).

(4) Computation of New Control: Using the evaluated $\nabla J(\boldsymbol{v})$ , an improved function is computed as

$$\boldsymbol{v}^{new} = \boldsymbol{v}^{old} + \nabla J(\boldsymbol{v}). \tag{48}$$

A single variable search strategy can be used to find the value of the positive weighting factor $w$ which maximizes the improvement in the performance functional using Equation (46) and (47).

(5) Termination: Go to Step (2) until reach the following stop criteria

$$\left| J^{new} - J^{old} \right| < \varepsilon, \tag{49}$$

where $\varepsilon$ is a small positive number.

It should be noted that the penalty function method is used to deal with the injection amount constraint and the terminal state constraint (23) and (24). The details of this method can refer to [12].

## V. Example

The two-phase flow of oil and water in a heterogeneous reservoir is considered. The reservoir covers an area of 421.02 × 443.8 $m^2$ and has a thickness of 5 $m$ and is discretized into 90 (9×10×1) grid blocks by finite difference method. There are four injection wells and a production well in reservoir as shown in Figure 1. Polymer is injected when the fractional flow of water for the production well comes to 97% after water flooding. In the performance index calculation, we use the price of oil $\xi_o = 0.0503\ (10^4\$/m^3)$ $[80\ (\$/\text{bbl})]$, and the cost of polymer $\xi_p = 2.5\times10^{-4}\ \ (10^4\$/kg)$. The fluid velocity of production well $q_{out}$ is 0.4624 $m/day$ and the fluid velocity of injection wells $q_{in}$ are all 0.1156 $m/day$. For the constraint (10), the maximum polymer concentration is $c_{\max} = 2.2\ (g/L)$. The parameters of the reservoir description and the fluid data are shown in Table I. Other parameters can refer to [11].

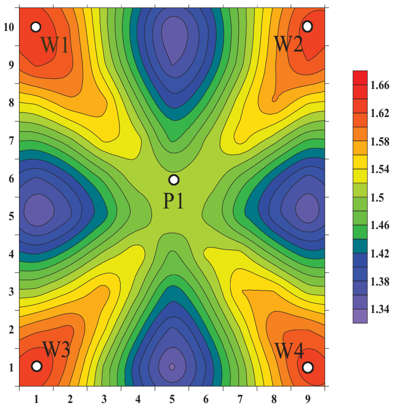

Figure 1. Permeability distribution and well position

The initial injection strategy obtained from engineering method is 1.7 $(g/L)$. The time domain of polymer injection is 0–1500 $days$. When the water fractional flow of production well reaches 98%, the terminal time $t_f = 5498\ (days)$. The performance index is $J = \$1.572\times10^7$ with oil production 32022 $m^3$ and polymer injection 153000 $kg$. For comparison, the results obtained by engineering method are considered as the initial control strategies of the proposed iterative gradient method. The maximum injection polymer amount is $m_{p\max} = 153000\ (kg)$. A backtracking search strategy [12] is used to find the appropriate weighting term $w$ and the stopping criterion is chosen as $\varepsilon = 1\times10^{-5}$. By using the proposed algorithm, we obtain a cumulative oil of 32750 $m^3$ and a cumulative polymer of 153000.02 $kg$ yielding the profit of $J^* = \$1.609\times10^7$. The results show an increase in performance index of \$ $3.7\times10^5$. The optimized terminal time is $t_f = 5165\ (days)$. Figure 2–5 show the injection strategies of the two methods. Figure 6 and Figure 7 show the curves of water fractional flow and accumulative oil production, respectively. The fractional flow of water obtained by proposed method is lower than that by engineering method. Therefore, with the same cumulative polymer injection, the proposed method gets more oil production and higher recovery ratio.

TABLE I. Reservoir Description and Fluid Data

## VI. Conclusion

In this work, a new optimal control model of DPS is established for the dynamic injection strategies making of polymer flooding. The original problem with free terminal time is transformed into a fixed terminal time OCP by introducing a normalized timer variable. Necessary conditions of this OCP are obtained by using Pontryagin's maximum principle. An iterative computational algorithm is proposed for the determination of optimal injection strategies. The optimal control model of polymer flooding and the proposed method are used for a reservoir example and the optimum injection concentration profile is offered. The results show that the profit is enhanced by the proposed method. Meanwhile, more oil production and higher recovery ratio are obtained. The approach used is a powerful tool that can aid significantly in the development of operational strategies for EOR processes.

*Abstract*—**This paper proposes a scheme for mixing enhancement in the boundary layers of pressure-driven membrane systems. This scheme uses an external electric field to activate the ions in the area adjacent to the membrane surface and generate an electro-osmotic flow. This scheme should reduce fouling and concentration polarization close to the membrane surface and may increase productivity of membrane systems. The objective of the feedback control design for this system needs to determine the voltage (and waveform) applied to the electrodes so that the electric field can effectively increase the mixing in the vicinity of membrane surface, while saving control power. This paper uses a mixing index in terms of the spatial gradients of the perturbation velocity field, which describes the mixing caused by both length stretching and folding. An optimal control problem is defined to maximize mixing in the area adjacent to the membrane and achieve control energy efficiency. In addition, the efficacy of the feedback scheme is validated by Computation Fluid Dynamics (CFD) simulation. The given control law not only solves the optimal problem but also provides the desired waveform for such applications.**

## I. Introduction

Most solid surfaces in contact with water or an aqueous solution will be found to develop some type of electrical charge. The mechanisms that a surface acquires an electrical charge include preferential solution of surface ions, direct ionization of surface groups, substitution of surface ions, specific ion adsorption and so on [1]. The electrical charges gather on the solid surface and form an electric double layer. Physically, the two layers of ions align on the surface and lead to concentration polarization. In the membrane system in seawater filtration or brackish water filtration, the membrane can considered as a solid surface. Concentration polarization will result in fouling formed on the surface of the membrane.

Fouling and concentration polarization reduce the throughput and productivity of membrane systems and significantly increase operating costs. This in turn reduces the profitability of water treatment processes including desalination and recycling. Despite much work and improvement in the design and operation of membrane systems, throughput and productivity continue to be plagued by fouling and concentration polarization. Amongst the mechanisms that have been proposed to reduce fouling and concentration polarization, for example, feed pre-treatment [2], membrane surface modification or cleaning [3], reduction of solute concentration at the membrane surface by mixing enhancement in the flow offers the most promising way. Mixing enhancement in the vicinity of membrane surface can reduce concentration polarization in the region and hence lessen the chance of forming fouling. As a result, the throughput of membrane increases. This paper proposes a new approach to the reduction of solute concentration and fouling at the membrane surface based on producing electro-osmotic flow (EOF) instability.

Electric field is able to activate the ions in a solution to induce an electro-osmotic flow. This paper uses this fact to develop a new approach which enhances the mixing in the area adjacent to the membrane surface, via the use of electric field to generate an EOF in this area. Many results on using electric field to motivate electro-osmotic flows have been reported, for example, [4], [5], [6], [7], [8]. Distinct from most of these results which moves the ions in the whole channel like flow transport, the electric field in this scheme will mostly act on the boundary layer close to the membrane surface, where concentration polarization and fouling occur. This should enable us to use less energy to achieve mixing enhancement and hence it may be more energy efficient than existing electro-kinetic methods.

As mentioned in [9], mixing includes several types: the mixing of a single or similar fluids caused by stretching and folding of fluid; the mixing governed by diffusion and chemical reaction; the mixing caused by breakup and coalescence of fluid. Due to the variety of reasons leading to mixing, there are different mixing indices. Amongst these types, the mixing caused by fluid stretching and folding is the one of interest in the context of this paper. To describe this type of mixing, [9] gives a strict definition of stretching length based on the gradient of relative velocity, which is an important measure of mixing. Specifically, this stretching length uses the stretching tensor to describe mixing. Alexiadis et al [10] uses the vorticity or spin gradient tensor to describe the mixing induced by the vortices (folding) in the circumstance of membrane channel containing circular spacers. This paper adds up these two mixing measures and establishes a new mixing index.

In [11], [12], an objective function involving turbulent kinetic energy and a measure of the spatial gradients of turbulent velocities is used as the cost functional of an optimal flow control problem and maximizing this cost functional leads

978-1-4673-1560-9/12/$31.00 ©2012 IEEE

to mixing enhancement. This cost functional includes a Frobenius norm of the gradient of relative velocity (perturbation velocity). This term reflects the stretching of fluid elements explicitly but the folding measurement is implicit. This term is positively related to mixing but it is not proportional to that of enstrophy which is said to be more related to mixing. In this paper, we further explore the Frobenius norm of the gradient of perturbation velocity and use it as our new mixing index.

The mixing enhancement within the area adjacent to the membrane surface leads to the increase of the throughput of the membrane. This suggests that the mixing within this small vicinity is much more important than that in the bulk solution; i.e., the effect of the electric field will mostly apply to the boundary layer of the system. In this paper, we focus our attention on the mixing enhancement in this rectangular area. This requires us to relate the boundary control action to the mixing in this area. Gauss's divergence theorem states that the outward flux of a vector field through a closed surface is equal to the volume integral of the divergence of the region inside the surface[13]. Based on Gauss's divergence theorem, [11], [12] proposes a heuristic flow control methods which convert a mixing increase problem in a 3D pipe to a boundary control problem. This paper relates the electric field close to the membrane surface to the perturbation velocity and their spatial gradients inside the surface and hence transforms the problem into a boundary control problem.

In addition, the electric field used to activate the fluid flow in the vicinity is generated from a pair of electrodes, which are installed outside the membrane. This restricts us from manipulating the distributive value of electric field when we construct the feeding voltage. Once the electrodes are fixed, the spatial distribution of this electric field is fixed, viz., the voltage will not affect the shape of this distribution. This paper uses the integral of electric field strength on the membrane surface to construct the feedback control law. This makes the results of this paper distinct from those in [12], where distributive flow injection is used.

To improve the energy efficiency, we integrate the perturbation kinetic energy, the new mixing index and the control effort to define a cost functional and formulate an optimal problem for the fluid flow control problem for membrane systems. This requires that the control candidates solve such an optimal problem and maximize the cost functional. In addition, the efficacy of the proposed mixing enhancement scheme and the given control law has been validated by CFD simulations. CFD is a widely used tool for the studies of membrane system. This reliable tool is utilized in order to gain insight into the phenomena taking place inside membrane modules, to assist the design process and improve the performance of modules.

This paper is organized as follows: Section 2 presents a new mixing index and the theory of enhancing mixing in the area adjacent to the membrane surface. This section includes the main results of this paper. Sections 3 uses CFD simulations to illustrate the efficacy of the newly developed mixing enhancement scheme and the control law; Section 4 gives a brief conclusion to the paper. To simplify our presentation, the proof of the main result is given in the Appendix.

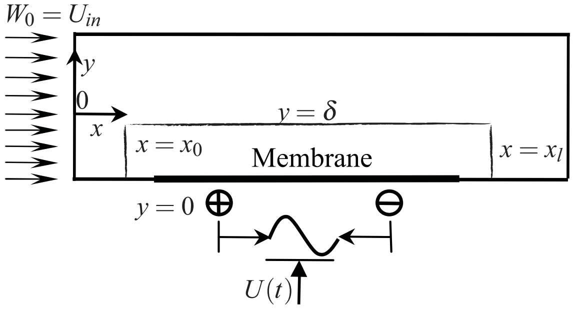

Fig. 1. The rectangular region close to the membrane surface.

## II. Optimal Feedback Control for Mixing Enhancement in the Boundary Layer of Membrane System

In this section, a special scheme is developed, which uses an external electric field to stir up the flow in the area adjacent to the membrane surface and thereby increase the mixing in this area. As mentioned above, different from the previous methods which increase mixing in the whole channel [11], the new method restricts the influence of the external electric field in a region adjacent to the boundary layer. The electrodes are installed outside the membrane and the electric field does not activate the bulk flow in the channel. This reduces energy consumption and brings economic advantages to engineering practice.

As shown in Fig.I, the system we consider in this paper contains a rectangular channel, a piece of membrane installed on the bottom wall and a pair of electrodes. The electrodes are installed to generate the required voltage. An ions solution is fed into the channel from its inlet. The purpose of this research is to develop a control algorithm which generates the voltage signal (voltage and waveform) applied to the electrodes.

This study aims to enhance the mixing of fluid flow in area adjacent to the membrane surface and thereby reducing fouling and concentration polarization on the membrane. Because the purpose of this research is to explore the effect of the electric field on the flow in the area, it is reasonable to assume that the membrane is impermeable in our simulation study. We also assume that the bulk flow in the channel is a laminar flow. In addition, we use the velocity gradient $\frac{\partial w_x}{\partial y}$ on the membrane surface as the measurements of our system to be controlled.

In the channel, fluid flow satisfies the Navier-Stokes equation and the continuity equation

$$\frac{\partial \mathbf{W}}{\partial t} + (\mathbf{W} \cdot \nabla)\mathbf{W} = -\frac{1}{\rho}\nabla P + \frac{\mu}{\rho}\Delta \mathbf{W}, \tag{1}$$

$$\operatorname{div}(\mathbf{W}) = 0. \tag{2}$$

We assume that a velocity field $(\overline{\mathbf{W}}, \overline{P}) = (\overline{W}_x, \overline{W}_y, \overline{W}_z, \overline{P})$ is a steady state solution of the equations (1) and (2) corresponding to fully developed laminar flow in the channel. The solution to the equations (1) and (2) can be obtained analytically. For example, $(6U_{in}(1-\frac{y^2}{h^2}), 0, 12\mu U_{in}\frac{L-x}{h^2})$ is a solution for the system in our simulation. Here, $U_{in}$ is the fluid velocity at the inlet of the channel, $\mu$ is the viscosity of the fluid, $h$ and $L$ are the height and the length of the channel. We can take these velocity components as the time-averaged values of the velocity field. Now, we define the perturbation variables

$$\mathbf{w} = (w_x, w_y, w_z) = \mathbf{W} - \bar{\mathbf{W}}, p = P - \bar{P}. \quad (3)$$

Substituting these variables into the equations (1) and (2), the Navier-Stokes equation and continuity equation become

$$\frac{\partial \mathbf{w}}{\partial t} + \left(\bar{\mathbf{W}} \cdot \nabla\right)\mathbf{w} + \left(\mathbf{w} \cdot \nabla\right)\bar{\mathbf{W}} + \left(\mathbf{w} \cdot \nabla\right)\mathbf{w} = -\frac{1}{\rho}\nabla p + \frac{\mu}{\rho}\Delta \mathbf{w}, \quad (4)$$

$$\operatorname{div}(\mathbf{w}) = 0. \quad (5)$$

in the domain $\Omega = \{(x,y,z) = [x_0,x_l] \times [-h/2, h/2]\}$ where $x_l - x_0$ is the length of the region we consider.

We define a rectangular prism $[x_0,x_l] \times [0,\delta]$, as shown in Fig. I, which contains all the flow being perturbed by the external electric field. Technically, it requires that the perturbation velocity components and the spatial gradients of the perturbation velocity field are all zeros on the surface $y = \delta$; i.e., the flow on and above this surface will not be perturbed by the electric field. Also, on the upstream and downstream sides of the rectangular prism, i.e., at $x = 0$ and $x = x_l$, the perturbation velocity components and the spatial gradients of the perturbation velocity field are also zero.

As the boundary condition on the membrane surface involves actuating the control law, it is worthy discussing the actuation scheme of the control at the first place. According to [5], [14], when an electric field is applied, the charges in the electric double layer induce fluid flow in the area adjacent to the membrane surface. As the boundary layer is very thin, the fluid flow on the membrane surface explains most effect of the electric field. Therefore, it is reasonable to assume that the external electric field only induces fluid flow on the membrane surface, rather than in $y$ direction. The induced flow velocity is called slip velocity $u_s$ and can be expressed as the product of electro-osmotic mobility $\mu_{EO}$ and the local electric field $E$ as $\overrightarrow{u}_s = \mu_{EO}\overrightarrow{E} = \frac{\varepsilon\zeta}{\mu}\overrightarrow{E}$ where $\zeta$ is the zeta potential, $\varepsilon$ is the permittivity, and $\mu$ is the viscosity of the fluid. In the context of this paper, the velocity $\overrightarrow{u}_s$ and the electric field $\overrightarrow{E}$ both take the $x$-axial direction as positive direction and the reverse direction as negative. Then, we write the slip velocity simply $u_s = \mu_{EO}E = \frac{\varepsilon\zeta}{\mu}E$. Therefore, the effect of the electric field on the fluid flow is transformed into a slip velocity on the membrane surface and the control problem becomes a boundary control problem.

Now, we can define the boundary condition for the equation (4). The equation (4) needs to satisfy the following boundary conditions on the rectangular prism $[x_0,x_l] \times [0,\delta]$

$x = x_0$: $w_x = 0$, $w_y = 0$, $\frac{\partial w_x}{\partial x} = 0$, $\frac{\partial w_x}{\partial y} = 0$, $\frac{\partial w_y}{\partial x} = 0$, $\frac{\partial w_y}{\partial y} = 0$;
$x = x_l$: ditto;
$y = \delta$: $w_x = 0$, $w_y = 0$, $\frac{\partial w_x}{\partial x} = 0$, $\frac{\partial w_x}{\partial y} = 0$, $\frac{\partial w_y}{\partial x} = 0$, $\frac{\partial w_y}{\partial y} = 0$;
$y = 0$: $w_x = u_s$, $w_y = 0$.

The boundary conditions on the surface $y = \delta$ are also the conditions for selecting $\delta$.

In this section, we assume that the measurement of the system to be controlled, $\frac{\partial w_x}{\partial y}|_{y=0}$ is known for constructing feedback control signal.

To facilitate the development of the new mixing enhancement approach, we define two concepts: perturbation kinetic energy and mixing index. The perturbation kinetic energy, which is equivalent to the turbulent kinetic energy as defined in [11] when turbulence is the main cause of mixing, is defined as

$$E(\mathbf{w}) = \frac{1}{2}\int_{\Omega} |\mathbf{w}|^2 dV = \frac{1}{2}\int_{x_0}^{x_l}\int_0^{\delta}\int_0^{z_r} \left(w_x^2 + w_y^2 + w_z^2\right) dxdydz. \quad (6)$$

The mixing in this paper is defined as a measure of the spatial gradients of the perturbation velocity field:

$$M(\mathbf{w}) = \int_{\Omega} |\nabla \mathbf{w}|^2 = \int_{\Omega} \mathrm{Tr}\{\nabla \mathbf{w}^T \nabla \mathbf{w}\} dV. \quad (7)$$

Previously, Ottino [9] defined a stretching mixing rates as

$$\frac{dL}{dt} = \int_{\Omega} Tr\left(\Phi^T \Phi\right) dV, \quad (8)$$

where $\Phi = \frac{1}{2}\left(\nabla \mathbf{w} + (\nabla \mathbf{w})^T\right)$.

Defining $\Psi = \frac{1}{2}\left(\nabla \mathbf{w} - (\nabla \mathbf{w})^T\right)$, then, the mixing estimation parameter in [10], which mainly reflects the extent of mixing caused by vortices, can be rewritten in the following form

$$\frac{d\Lambda}{dt} = \int_{\Omega} Tr\left(\Psi^T \Psi\right) dV. \quad (9)$$

It is obvious that (7) is the sum of (8) and (9):

$$M(\mathbf{w}) = \int_{\Omega} |\nabla \mathbf{w}|^2 dV = \int_{\Omega} \mathrm{Tr}\left(\Phi^T \Phi\right) dV + \int_{\Omega} \mathrm{Tr}\left(\Psi^T \Psi\right) dV$$

That is, the mixing index (7) describes the mixing caused by both length stretching and folding induced by perturbations.

The proposed mixing enhancement scheme uses electric field to induce perturbations to the boundary layer. Fluid stretching and vortices account for most of the mixing caused by the perturbations. Therefore, the new mixing index can be used to describe the extent of the mixing caused by the perturbation in the circumstance of this paper. It is worth pointing out that this mixing index describes the mixing enhancement due to the perturbation caused by EOF and it does not reflect mixing inherent in the steady-state system and related to the original velocity gradients and momentum diffusion.

The control actuation of the proposed scheme is implemented through a pair of fixed electrodes and this gives the electric field a special distribution. This makes the proposed methods distinct from the flow control scheme in the literatures, for example, [12]. Based on aforementioned actuation mechanism, the slip velocity

$$u_s = U(t)f(x), \quad (10)$$

where $U(t)$ is the voltage applied to the electrodes, which is generated from our control algorithm, and

$$f(x) = C_1 \left[ \frac{x - l_1}{(x - l_1)^2 + C_2} - \frac{x - l_2}{(x - l_2)^2 + C_2} \right]$$

describes the distribution of the electric field with the parameters $C_1 = \frac{\varepsilon_w \zeta}{2\mu \ln\left(\frac{l_{i,2} - l_{i,1} - r_c}{r_c}\right)}$, and $C_2 = (h_m + r_c + \Delta y)^2$. Here, $r_c$ is the radius of electrodes, $h_m$ is the thickness of membrane and $\Delta y$ is the distance between the electrode and the membrane outside. The other constants $\varepsilon_w$, $\zeta$, $\mu$ are the permittivity, zeta potential, viscosity, respectively. Define $F = \int_0^{x_l} f^2(x)dx$, then

$$\begin{aligned} F = & \int_0^{x_l} C_1^2 \left[ \frac{x - l_1}{(x - l_1)^2 + C_2} - \frac{x - l_2}{(x - l_2)^2 + C_2} \right]^2 dx \\ = & C_1^2 \int_0^{x_l} \left[ \frac{x - l_1}{(x - l_1)^2 + C_2} \right]^2 dx - 2C_1^2 \int_0^{x_l} \frac{x - l_1}{(x - l_1)^2 + C_2} \times \\ & \frac{x - l_2}{(x - l_2)^2 + C_2} dx + C_1^2 \int_0^{x_l} \left[ \frac{x - l_2}{(x - l_2)^2 + C_2} \right]^2 dx. \end{aligned} \tag{11}$$

Now, we calculate the term on the right side of the equation (11) one by one. First we calculate the first term on the right side of (11). From the fact that $\left[\frac{x-l_1}{(x-l_1)^2+C_2}\right]^2 = \left[\frac{Ax+B}{(x-l_1)^2+C_2}\right]' + \left[\frac{Cx+D}{(x-l_1)^2+C_2}\right]$ where $A = -\frac{1}{2}$, $B = \frac{1}{2}l_1$, $C = 0$, $D = \frac{1}{2}$ and '$'$' means derivative, it follows that $\int_0^{x_l} C_1^2 \left[\frac{x-l_1}{(x-l_1)^2+C_2}\right]^2 = \left[\frac{-1/2x+1/2}{(x-l_1)^2+C_2}\right]_0^{x_l} + \frac{1}{2\sqrt{C_2}} \arctan \frac{x}{2\sqrt{C_2}} \Big|_{-l_1}^{x_l - l_1} = -\frac{x_l - 1}{2(x_l - l_1)^2 + 2C_2} - \frac{1}{2(l_1^2 + C_2)} + \frac{1}{2\sqrt{C_2}} \arctan \frac{x_l - l_1}{2\sqrt{C_2}} - \frac{1}{2\sqrt{C_2}} \arctan \frac{-l_1}{2\sqrt{C_2}}$. In the same way, we have

$$\begin{aligned} & \int_0^{x_l} \left[ \frac{x - l_2}{(x - l_2)^2 + C_2} \right]^2 dx = \left[ \frac{-1/2x + 1/2}{(x - l_2)^2 + C_2} \right]_0^{x_l} \\ & + \frac{1}{2\sqrt{C_2}} \arctan \frac{x}{2\sqrt{C_2}} \Big|_{-l_2}^{x_l - l_2} \\ & = -\frac{x_l - 1}{2(x_l - l_2)^2 + 2C_2} - \frac{1}{2(l_2^2 + C_2)} + \frac{1}{2\sqrt{C_2}} \arctan \frac{x_l - l_2}{2\sqrt{C_2}} \\ & - \frac{1}{2\sqrt{C_2}} \arctan \frac{-l_2}{2\sqrt{C_2}}. \end{aligned}$$

The second term on the right side of (11) $\frac{x-l_1}{(x-l_1)^2+C_2} \times \frac{x-l_2}{(x-l_2)^2+C_2} = \frac{Ax+B}{(x-l_1)^2+C_2} + \frac{Cx+D}{(x-l_2)^2+C_2}$ where $A = 0$ and $B$, $C$, $D$ are the solution of the following linear equations

$$\begin{bmatrix} 2(l_2 - l_1) & 1 & 1 \\ l_1^2 - l_2^2 & -2l_2 & -2l_1 \\ 0 & l_2^2 + C_2 & l_1^2 + C_2 \end{bmatrix} \begin{bmatrix} C \\ B \\ D \end{bmatrix} = \begin{bmatrix} 2 \\ -2(l_1 + l_2) \\ 2l_1 l_2 \end{bmatrix}.$$

Then, we can calculate $\int_0^{x_l} \frac{x-l_1}{(x-l_1)^2+C_2} \times \frac{x-l_2}{(x-l_2)^2+C_2} dx = \frac{B}{\sqrt{C_2}} \arctan \frac{x}{2\sqrt{C_2}} \Big|_{-l_1}^{x_l - l_1} + C\frac{1}{2} \ln[(x - l_1)^2 + C_2]_0^{x_l} + (D - Cl_2)\frac{1}{C_2} \arctan \frac{x}{2\sqrt{C_2}} \Big|_{-l_2}^{x_l - l_2}$ and thus $F$ can be integrated analytically. From the above calculation, we can see that if the electrodes are installed, the distribution of the strength of the external electric field has been determined and $F$ is a constant; i.e., the voltage is the only design variable of the electric field.

Now, we define the main problem to be solved in this section:

**Problem A:** The optimal feedback control problem is defined as finding an appropriate $U(t)$ for the control law $u_s(x,t) = U(t)f(x)$, to maximize the following cost functional

$$\begin{aligned} J(u) = \lim_{t \to \infty} \Bigg[ & E(\mathbf{w}(t)) + \int_0^t \Bigg( \frac{\mu}{\rho} M(\mathbf{w}) + \Gamma(\mathbf{w}(t)) \\ & - \alpha \int_{\bar{\Omega}} u_s^2(\tau) dA - \frac{\mu^2}{4\rho^2 F \alpha} \left( \int_{\bar{\Omega}} f(x) \frac{\partial w_x}{\partial y}(\tau) dA \right)^2 \Bigg) d\tau \Bigg]. \end{aligned} \tag{12}$$

where $\bar{\Omega}$ is the surface $y = 0$, and $\alpha > 0$ is a constant related to the amplitude of $U(t)$, which is used to adjust the applied voltage.

In the cost functional (12), the first term describes the perturbation kinetic energy of the flow; the second term is the mixing index; the third term describes the stretching caused by laminar flow and its definition is given in the Appendix The rest two terms will be explained in the following.

The following theorem gives a solution to Problem A:

*Theorem 1:* Given a constant $\alpha > 0$, the control law

$$U(t) = -\frac{\mu}{2\rho \alpha F} \int_{\bar{\Omega}} f(x) \frac{\partial w_x}{\partial y} dA \tag{13}$$

solves Problem A. Also, the slip velocity

$$u_s(x,t) = -\frac{\mu}{2\rho \alpha F} f(x) \left( \int_{\bar{\Omega}} f(x) \frac{\partial w_x}{\partial y} \right) dA \tag{14}$$

is the boundary condition on the lower wall of the channel in the system (4) and (5).

The proof of this theorem is given in the Appendix.

Here, $U(t)$ is a continuous signal. The amplitude of this voltage signal is $U_A = \| \frac{\mu\lambda}{2\rho} \left( \int_{\bar{\Omega}} f(x) \frac{\partial w_x}{\partial y} \right) / F \|$. Here, the formula of $U(t)$ is not an explicit function of time $t$ but the system dynamics behind $\frac{\partial w_x}{\partial y}$ implies $U(t)$ is a function of $t$. The term $\frac{\partial w_x}{\partial y}$ itself is a function of time. In the area close to the membrane surface, the absolute perturbation velocity $|w_x|$ decreases in $y$ direction and hence the sign $\frac{\partial w_x}{\partial y}$ is opposite to that of $w_x$. Since the output is fed back to the control input, the output penalty works in conjunction with the input penalty to minimize control effort.

## III. Simulations and Mixing measurements

In this section, the fluid dynamics of the EOF in a membrane system are simulated using ANSYS CFX to validate the efficacy of the control feedback approach; i.e., to test the effect of mixing enhancement in the vicinity of the membrane.

In the simulation, we consider the $2D$ case and use a channel with $L = 0.11$m and height $h = 0.004$m. The electrodes are cylindrical and $h_m = 0.00025$m, $r_c = 0.005$m. The distance between the two electrodes is 0.015m.

Because the purpose of the simulation is to validate the mixing enhancement in the area adjacent to the membrane surface when the electric field is applied, we assume that the membrane is impermeable. In our simulation, we also used the following parameters for the system: $h_m = 0.00025$m, $\mu = 0.001\text{kg}\cdot\text{m}^{-1}\cdot\text{s}^{-1}$, $\rho = 1000\text{kg}\cdot\text{m}^{-3}$, $\zeta = 0.02\text{kg}\cdot\text{m}^2\cdot\text{s}^{-3}\cdot\text{A}^{-1}$, $r_c = 0.005$m, $\varepsilon_w = 7.0832\times10^{-10}\text{m}^{-3}\cdot\text{kg}^{-1}\cdot\text{s}^4\cdot\text{A}^2$. The feeding flow velocity to the channel is a typical velocity in membrane systems used in water treatment, $\bar{W}_x = 0.14\text{m}\cdot\text{s}^{-1}$. In our simulation, the constant is selected as $\alpha = 0.008$, the Reynolds number of the flow is 280, and the step time is $10^{-5}$s.

To give the system an initial perturbation, we first apply an oscillating voltage to the system, and then run the CFD simulation using the feedback control law given in this paper. The feedback is calculated using (13). As shown in Fig. 2, the simulation results show that the feedback oscillates around zero over time. The mixing extent caused by the electric field is measured by $M(\mathbf{w})$, which is the integral of spatial gradients of the perturbation velocity field over $\Omega$. As the electric field is the only perturbation in the channel, $\Omega$ is selected as to contain all the perturbations in the channel. Fig. 3 shows the mixing effect of the mixing enhancement scheme, in comparison with case without electric field ($M(\mathbf{w}) = 0$). The mixing index has a scale of $10^{-6}$) in Fig. 3. This is because the system itself has a scale of $10^{-6}$. As shown in Fig. 3, the mixing index also has oscillating features and this shows that the mixing is caused by the input voltage. Therefore, this illustrates the efficacy of the proposed mixing enhancement scheme and control law.

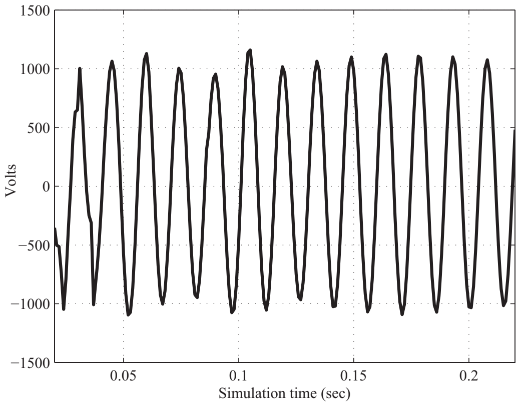

Fig. 2. The feedback control signal of the closed-loop system.

## IV. Conclusion

This paper has proposed a method for mixing enhancement in the vicinity of the membrane surface and increasing the productivity of the membrane system. A new mixing index has been defined and incorporated into the cost functional of an optimal control problem. This paper uses the integral of an electric field distribution function to handle the actuation problem due to fixed electric field distribution and distributive slip velocity. An optimal control problem has been defined in this paper and the control law given in this paper solves this optimal problem and maximizes the cost functional. A CFD simulation has been used to demonstrate the effect of the control law on mixing in the vicinity area adjacent to the membrane and has illustrated the efficacy of the proposed method. It also illustrates that the control law gives the desired waveform for such applications.

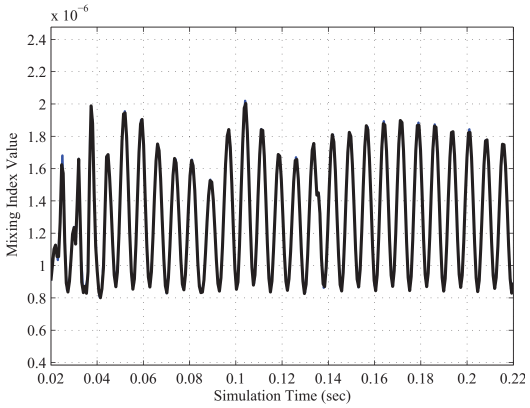

Fig. 3. The mixing index value when the control law (13) is applied to the system.

## Appendix

### A. Proof of Theorem 1:

The proof includes two parts: calculating the derivative of turbulent kinetic energy and verifying that the control maximizes the cost functional (12). We first consider the time derivative of the perturbation kinetic energy

$$\begin{aligned}\beta = \frac{d}{dt}E(\mathbf{w}) &= \int_\Omega \frac{\partial \mathbf{w}}{\partial t}\cdot\mathbf{w}dV\\ &= -\int_\Omega \left(\left(\bar{\mathbf{W}}\cdot\nabla\right)\mathbf{w} + \left(\mathbf{w}\cdot\nabla\right)\bar{\mathbf{W}}\right)\cdot\mathbf{w}dV - \int_\Omega \left(\mathbf{w}\cdot\nabla\right)\mathbf{w}\cdot\mathbf{w}dV\\ &\quad - \int_\Omega \frac{1}{\rho}\nabla p\cdot\mathbf{w}dV + \int_\Omega \frac{\mu}{\rho}\Delta\mathbf{w}\cdot\mathbf{w}dV. \qquad (15)\end{aligned}$$

Now, we consider the terms on the right side one by one.

$$\begin{aligned}-\int_\Omega \left(\mathbf{w}\cdot\nabla\right)\mathbf{w}\cdot\mathbf{w}dV &= -\frac{1}{2}\int_\Omega \nabla(\mathbf{w}\cdot\mathbf{w})\mathbf{w}dV\\ &= -\frac{1}{2}\int_\Omega \operatorname{div}\left((\mathbf{w}\cdot\mathbf{w})\mathbf{w}\right) = -\frac{1}{2}\int_{\partial\Omega}\left[(\mathbf{w}\cdot\mathbf{w})\mathbf{w}\right]\cdot\mathbf{n}dA.\end{aligned}$$

On the surfaces $x = x_0, x = x_l$ and $y = \delta$, $\mathbf{w} = [w_x; w_y] = 0$. This results that $[(\mathbf{w}\cdot\mathbf{w})\mathbf{w}] = 0$. As $\mathbf{w}$ is perpendicular to $\mathbf{n}$ on the surface $y = 0$, the right side of the above equality is equal to zero. Therefore, $-\int_\Omega (\mathbf{w}\cdot\nabla)\mathbf{w}\cdot\mathbf{w}dV = 0$.

By the divergence theorem of Gauss, $-\frac{1}{\rho}\int_\Omega \nabla p\cdot\mathbf{w}dV = -\frac{1}{\rho}\int_\Omega \operatorname{div}(p\mathbf{w})\,dV = -\frac{1}{\rho}\int_{\partial\Omega} p\mathbf{w}\cdot\mathbf{n}dA$. As $\mathbf{w} = 0$ on the surfaces $x = x_0, x = x_l$ and $y = \delta$ and the fact that $\mathbf{w}\cdot\mathbf{n} = 0$ on the surface $y = 0$, we have $-\frac{1}{\rho}\int_\Omega \nabla p\cdot\mathbf{w}dV = 0$.

Consider the fourth term on the right side of (15). Using the Einstein summation notation, $\int_\Omega \frac{\mu}{\rho}\Delta\mathbf{w}\cdot\mathbf{w}dV = -2\nabla w_i\cdot\nabla w_i - w_i(\Delta w_i)]dV = \frac{\mu}{\rho}\int_\Omega \frac{1}{2}\Delta(w_i w_i)dV - \frac{\mu}{\rho}\int_\Omega |\nabla w|^2 dV$.

The term $\frac{1}{2}\frac{\mu}{\rho}\int_\Omega \Delta(w_i w_i)dV = \frac{1}{2}\frac{\mu}{\rho}\int_{\partial\Omega}(\nabla|\mathbf{w}|^2)\cdot\mathbf{n}dA$. On $\partial\Omega$, as $\mathbf{w} = 0$ on the surfaces $x = x_0, x = x_l$ and $y = \delta$, we only need to consider the surface $y = 0$ where $\mathbf{n} = -j$. From the fact that $w_y|_{y=0} = 0$, it follows that

$$\frac{1}{2}\frac{\mu}{\rho}\int_{\Omega}\Delta(w_i w_i)dV$$
$$= -\frac{1}{2}\frac{\mu}{\rho}\int_0^{z_r}\int_{x_0}^{x_l} 2\left(w_x\frac{\partial w_x}{\partial y} + w_y\frac{\partial w_y}{\partial y}\right)_{y=0} dxdz$$
$$= -\frac{\mu}{\rho}\int_0^{z_r}\int_{x_0}^{x_l}\left(w_x\frac{\partial w_x}{\partial y}\right)_{y=0} dxdz.$$

Let $\Gamma = \int_{\Omega}((\bar{W}\cdot\nabla)w + (w\cdot\nabla)\bar{W})\cdot wdV$. Consider that $\bar{W}_y = \frac{\partial \bar{W}_y}{\partial y} = \frac{\partial \bar{W}_y}{\partial x} = 0$ and our problem is two dimensional, we have

$$\Gamma(\mathbf{w}) = \int_{\Omega}\left(\bar{W}_x\frac{\partial w_x}{\partial x}w_x + \bar{W}_x\frac{\partial w_y}{\partial x}w_y + w_y\frac{\partial \bar{W}_x}{\partial y}w_x\right)dV.$$

Then, we can conclude that

$$\frac{dE(\mathbf{w}(t))}{dt} = -\Gamma(\mathbf{w}) - \frac{\mu}{\rho}\int_0^{z_r}\int_0^{l} w_x\frac{\partial w_x}{\partial y}|_{y=0}dxdz - \frac{\mu}{\rho}M(\mathbf{w}).$$

Now, we substitute this result into the cost functional (12) and prove that the control law (13) maximizes this cost functional.

$$\frac{1}{2}\frac{\mu}{\rho}\int_{\Omega}\Delta(w_i w_i)dV$$
$$= -\frac{1}{2}\frac{\mu}{\rho}\int_0^{z_r}\int_{x_0}^{x_l} 2\left(w_x\frac{\partial w_x}{\partial y} + w_y\frac{\partial w_y}{\partial y}\right)_{y=0} dxdz$$
$$= -\frac{\mu}{\rho}\int_0^{z_r}\int_{x_0}^{x_l}\left(w_x\frac{\partial w_x}{\partial y}\right)_{y=0} dxdz.$$

Let $\Gamma = \int_{\Omega}((\bar{W}\cdot\nabla)w + (w\cdot\nabla)\bar{W})\cdot wdV$. Consider that $\bar{W}_y = \frac{\partial \bar{W}_y}{\partial y} = \frac{\partial \bar{W}_y}{\partial x} = 0$ and our problem is two dimensional, we have

$$\Gamma(\mathbf{w}) = \int_{\Omega}\left(\bar{W}_x\frac{\partial w_x}{\partial x}w_x + \bar{W}_x\frac{\partial w_y}{\partial x}w_y + w_y\frac{\partial \bar{W}_x}{\partial y}w_x\right)dV.$$

Then, we can conclude that

$$\frac{dE(\mathbf{w}(t))}{dt} = -\Gamma(\mathbf{w}) - \frac{\mu}{\rho}\int_0^{z_r}\int_0^{l} w_x\frac{\partial w_x}{\partial y}|_{y=0}dxdz - \frac{\mu}{\rho}M(\mathbf{w}).$$

Now, we substitute this result into the cost functional (12) and prove that the control law (13) maximizes this cost functional.

$$J(u_s) = \lim_{t\to\infty}\left[E(\mathbf{w}(t)) + \int_0^t\left(-\frac{dE(\mathbf{w}(t))}{d\tau} - \Gamma(\mathbf{w}(t))\right.\right.$$
$$-\frac{\mu}{\rho}\int_{\bar{\Omega}}u_s\frac{\partial w_x}{\partial y}|_{y=0}dA + \Gamma(\mathbf{w}(t)) - \alpha\int_{\bar{\Omega}}u_s^2(\tau)dA$$
$$\left.\left.-\frac{\mu^2}{4\rho^2F\alpha}\left(\int_{\bar{\Omega}}f(x)\frac{\partial w_x}{\partial y}(\tau)|_{y=0}dA\right)\right)^2 d\tau\right]$$
$$= E(\mathbf{w}(0)) + \lim_{t\to\infty}\left[\int_0^t\int_{\bar{\Omega}}\left(-\frac{\mu}{\rho}u_s(\tau)\frac{\partial w_x}{\partial y}|_{y=0}dA\right.\right.$$
$$-\alpha\int_{\bar{\Omega}}u_s^2(\tau)dA$$
$$\left.\left.-\frac{\mu^2}{4\rho^2F\alpha}\left(\int_{\bar{\Omega}}f(x)\frac{\partial w_x}{\partial y}(\tau)|_{y=0}\right)dA\right)^2 d\tau\right].$$

Furthermore, we have

$$J(u_s) = E(\mathbf{w}(0)) + \lim_{t\to\infty}\left[\int_0^t\left(\frac{\mu}{\rho}\int_{\bar{\Omega}}-U(t)f(x)\frac{\partial w_x}{\partial y}|_{y=0}dA\right.\right.$$
$$\left.\left.-\alpha U(t)^2F - \frac{\mu^2}{4\rho^2F\alpha}\left(\int_{\bar{\Omega}}f(x)\frac{\partial w_x}{\partial y}(\tau)|_{y=0}dA\right)^2\right)d\tau\right]$$
$$= E(\mathbf{w}(0)) + \lim_{t\to\infty}\alpha F\int_0^t\left[-\frac{U(t)}{\alpha F}\left(\frac{\mu}{\rho}\int_{\bar{\Omega}}f(x)\frac{\partial w_x}{\partial y}|_{y=0}\right)dA\right.$$
$$\left.-U(t)^2 - \frac{\mu^2}{4\rho^2\alpha^2F^2}\left(\int_{\bar{\Omega}}f(x)\frac{\partial w_x}{\partial y}(\tau)|_{y=0}dA\right)^2\right]d\tau$$
$$= E(\mathbf{w}(0))$$
$$-\lim_{t\to\infty}F\int_0^t\left(U(t) + \frac{\mu}{\rho}\frac{1}{2\alpha F}\int_{\bar{\Omega}}f(x)\frac{\partial w_x}{\partial y}|_{y=0}dA\right)^2 d\tau. \quad (16)$$

When $U(t) = -\frac{\mu}{2\rho\alpha F}\int_{\bar{\Omega}}f(x)\frac{\partial w_x}{\partial y}|_{y=0}dA$, the integral in (16) is zero. Then, the maximum of (12) is achieved. Therefore, (14) holds. This completes the proof. □

# *Adaptive Feed-Forward and Feedback Control for Oxygen Ratio in Fuel Cell Stacks*

Omar Ragb, D L YU and JB Gomm
Control system research group, School of Engineering
Liverpool John Moore University
Liverpool, UK
om.khazali_yo@yahoo.com

*Abstract*—**Automatic control of fuel cell stacks (FCS) using non-adaptive and adaptive radial basis function (RBF) neural network methods are investigated in this paper. The neural network RBF inverse model is used to estimate the compressor voltage for fuel cell stack control at different current demands, reduction in the compressor gain (30% and 20%) and manifold leak (15%) in order to prevent the oxygen starvation. A PID controller is used in the feedback to adjust the difference between the requested and the actual oxygen ratio by compensating the neural network inverse model output. This method is designed and conducted in three stages, starting with the collection of data from the available fuel cell stack model and finished with the non adaptive and adaptive RBF neural network control. RBF neural networks with the K-means and P-nearest Neighbour's training algorithms are used for the investigation. Furthermore, the RBF inverse model is made adaptive to cope with the significant parameter uncertainty, disturbances and environment changes. Simulation results show the effectiveness of the adaptive control strategy.**

## I. Introduction

Burning current natural sources causes many environment problems today. A lot of harmful gases, such as $CO_2$, rise in the environment as a result of burning fossil fuels and destructs the ozone layer, which leads to climatic change and what is known as the greenhouse effect. To recover this problem, the world has been looking for energy sources that are clean and safe on the environment. Fuel cells are a kind of clean and safe energy source on the environment. Polymer electrolyte membrane (PEM) fuel cells emerge as one of the most clean and promising alternatives to reduce fossil fuel dependency [1]. In the last years many researchers have presented some methods to control the fuel cell stacks, in order to prevent the oxygen starvation and improve the fuel cell control, which are now reviewed. Sedighizadeh M. [2] discussed the application of wavelet networks in the implementation of adaptive controllers for PEMFC's. Jiang Z. et al. [3] presented an adaptive control strategy for active power sharing in the hybrid power source. This control strategy is able to adjust the output current set-point of the fuel cell according to the state of the charge (or voltage) of the battery. An adaptive MPPT controller using the extrermum-seeking algorithm [4] is used to automatically keep the fuel cell working at maximum power point (MPP) all the time. Fiacchini M. et al. [5] is presented an adaptive control scheme for the safe operation of a fuel cell system. In particular, the aim of control action is to avoid that the oxygen ratio reaches dangerous values. In this paper adaptive and non-adaptive control methods are implemented to achieve better control for the fuel cell breathing. Furthermore, in this paper, we first explain the fuel cell working principles followed by description of the dynamic model of fuel cell stacks. We then formulate the RBF adaptive and non adaptive model. Finally we demonstrate simulation results for the fuel cell control with adaptive and non adaptive controllers.

## II. Fuel cell Dynamics

### *A. Fuel Cell Working and prenceples*

Fuel cells consume a hydrogen fuel (on the anode side) and oxygen (on the cathode side) and produce electric energy with water and some heat through a chemical reaction [1], to satisfy different power requirements (Fig. 1). Generally, the reactants flow in and reaction products flow out while the electrolyte remains in the cell. Fuel cells differ from batteries in that they do not need recharging, they operate quietly and efficiently, and when hydrogen is used as fuel they generate only electric power and drinking water. So, they are called zero emission engines. William Grove discovered the basic operating principle of fuel cells by reversing water in 1839 [6]. In particular, proton exchange membrane fuel cells (PEM-FCs), also known as polymer electrolyte membrane fuel cells, are considered to be more developed than other fuel cells technologies, because they have high power density, solid electrolyte, operate at low temperature, long cell and stack life and low corrosion [6]. The PEM-FC takes its name from the special plastic membrane used as the electrolyte. This membrane electrode assembly (MEA), not thicker than a few hundred microns, is the heart of a PEM-FC and, when supplied with fuel and air, generates electric power at cell voltages around 0.7 Volt and power densities of up to about 1 W/cm electrode area. Fig. 2 shows a schematic of a PEM-FCS and MEA. The MEA is typically located between a pair of current collector plates (platinum-impregnated porous electrodes) with machined flow fields for distributing fuel and oxidant to the

Omar AL-Mukhtar University, Libya

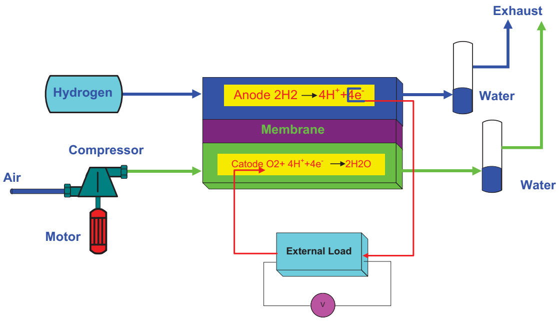

Figure 1. PME- FC reaction and structure

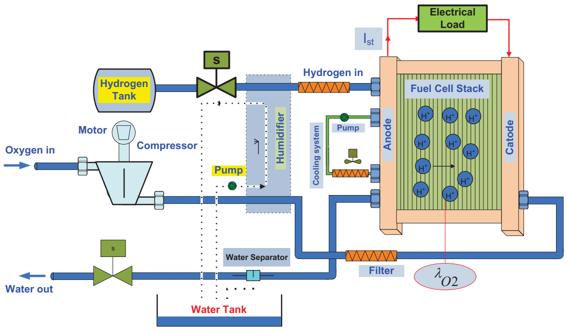

Figure 2. PEM fuel cell structure

anode and cathode, respectively. A water jacket for cooling is often placed at the back of each reactant flow field followed by a metallic current collector plate. The cell can also contain a humidification section for the reactant gases, which are kept close to their saturation level in order to prevent dehydration of the membrane electrolyte. Many FCs are connected electrically in series (Fig. 2) to form an FC stack (FCS).

### B. *Fuel Cell Stack Model*

The fuel cell stack (FCS) model simulated in this paper consists of four interacting sub-models (Fig. 3) which are the stack voltage, the anode flow, the cathode flow, and the membrane hydration models [6]. The voltage model contains an equation to calculate stack voltage based on fuel cell temperature, pressure, reactant gas partial pressures and membrane humidity, in summary, the fuel cell voltage *E* is given by

$$E = 1.2229 - 0.85\times10^{-3}(T_{fc} - 29815) + 43085\times10^{-5}T_{fc}(p_{H2}) + \frac{1}{2}p_{O2} \quad (1)$$

where, $T_{fc}$ is the fuel cell temperature in Kelvin, $p_{H2}$ and $p_{O2}$ are the partial pressures of hydrogen and oxygen respectively, details in [1,6]. In this model the stack temperature is assumed to be constant at 80°C. The model which is used in our investigations is given in [6]. The FCS Simulink model is created in Matlab 6.5.

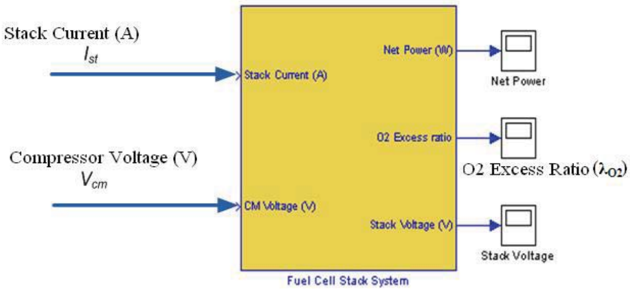

Figure 3. Simulink model of integrated PEM fuel cell

## III. FEED-FORWARD CONTROL DESIGN BASED ON NN

### A. *NN Inverse Model*

The radial basis function neural network (RBFNN) has an ability to model any non-linear function. However, this kind of neural network can need many nodes to achieve the required approximating properties [7]. The first step in the fuel cell modelling is the generation of a suitable training data set. The accuracy of the neural network modelling performance will be influenced by the training data. In the fuel cell stack data collection, the training data must be representative fuel cell behavior in order to analyze the performance of RBF fuel cell models in practical operating conditions. This means that input and output signals should sufficiently cover the region in which the system is going to be controlled [8]. As shown in Fig. 3, the fuel cell stack used for this research has to inputs compressor voltage $v_{cm}$ and the load current $I_{st}$, has three outputs (stack voltage *SV*, net power *NP* and oxygen ratio $y=O_2$). A set of random amplitude signals (RAS) were designed (0~3000 samples) for the fuel cell current load demand ($I_{st}$) and the compressor voltage ($v_{cm}$) to obtain a representative set of input data. The RASs of the current load demand and fuel cell compressor voltage were bounded between 100 and 300 Ampere for the current and between 100 and 235 volts for the compressor voltage see table I. Appling these two random input signals on the fuel cell model produces three outputs which are oxygen ratio (*y*), stack voltage (*SV*) and net power (*NP*) see table II and Fig. 4.

TABLE I. RAS INPUTS SIGNAL FOR $\hat{v}_{cm}$ MODELLING

| Parameters | Minimum | Maximum |
|---|---|---|
| $V_{cm}$ | 100 Volts | 235 Volts |
| $I_{st}$ | 100 | 300 |

TABLE II. OUTPUTS SIGNAL FOR $\hat{v}_{cm}$ MODELLING

| Parameters | Minimum | Maximum |
|---|---|---|
| $y=O_2$ | 0.7051 | 5.24 |
| SV | 112.64 Volts | 282.79 Volts |
| PN | 3850 | 6630 |

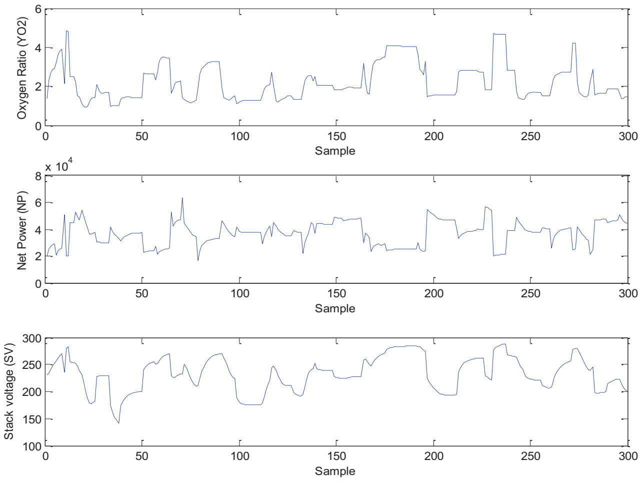

Figure 4. Fuel cell stack parameters output after applied RAS of $I_{st}$ & $v_{cm}$

For RBF neural network training, the K-means algorithm is used to choose the centers, $\rho$-nearast neighbor algorithm decides the widths and the recursive training algorithm [9] calculates the weights for the output layer. Here, a RBFNN based inverse model is used to predict the compressor voltage $\hat{v}_{cm}(k)$ which is the manipulated variable in the next sample time.The RBFNN block diagram is illustrated in Fig. 5, where the RBFNN input at sample $k$ is a vector $x(k)$ it also given by the following equation:

$$x(k) = [v_{cm}(k-1)\ y(k-1)\ I_{st}(k)\ I_{st}(k-1)\ SV(k-1)$$

$$PN(k-1)\ PN(k-2)\ PN(k-3)]^T \tag{2}$$

The neural network output is:

$$\hat{v}_{cm}(k) = g[v_{cm}(k-1)\, y(k-1)\, I_{st}(k)\, I_{st}(k-1)$$

$$SV(k-1)\, N(k-1)\, PN(k-2)\, PN(k-3)] \tag{3}$$

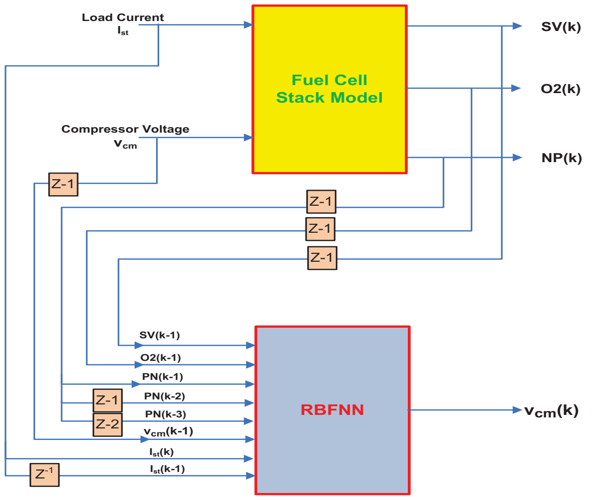

Figure 5. The RBFNN block diagram with Input variables

where g(.) is the nonlinear neural network function and $\hat{v}_{cm}(k)$ is the estimated compressor voltage. In order to train this neural network model, RASs were applied to the two fuel cell stack inputs $I_{st}$ and $v_{cm}$ and data for the fuel cell were collected for $O_2$, $SV$ and $PN$ at each sample time. The raw data were scaled using the following equation before training:

$$xscale(k) = \frac{x(k) - \min\{x(i)\}}{\max\{x(i)\} - \min\{x(i)\}} \qquad i \in [1, N]$$

The training data set with 2000 samples are used to train the RBFNN model. Then, the test set with 1000 is applied to the trained model and the model output prediction results are displayed in Fig. 6. The mean absolute error (MAE) is used to evaluate the modelling and control performance in this research, which is given by the following equation:

$$MAE = \frac{1}{N}\sum_{k=1}^{N}\left|\hat{v}_{cm}(k) - v_{cm}(k)\right| = \frac{1}{N}\sum_{k=1}^{N}\left|e(k)\right| \tag{5}$$

where $\hat{v}_{cm}(k)$ is the prediction by the inverse neural network model and $v_{cm}$ is the compressor voltage. The $\hat{v}_{cm}(k)$ in Fig. 6 is the normalized value and the MAE is 0.0142. The output of the neural network is nearly equal to the actual compressor voltage input. This is because $y(k-1)$, which can be calculated online at sample time $k$, was also used to predict the value of compressor voltage $\hat{v}_{cm}(k)$. Also this inverse RBFNN model can predict the required $\hat{v}_{cm}(k)$ for one sample step. The $\hat{v}_{cm}(k)$ can be calculated according to (3).

### B. *Non-Adaptive FF and FB Control Scheme*

The RBFNN-based non-adaptive feed-forward with feedback control system structure in our implementation is shown in Fig. 7. After trained the RBFNN inverse model and we got satisfy results. So, all the Recursive Least Square parameters ($w(0)$,µ and $\rho(0)$ will be saved in order to use them in non-adaptive and adaptive feed-forward controllers, then we will use this model in the feed-forward path to predict the scaled compressor voltage $\hat{v}_{cm}(k)$ and is given by (6).

$$\hat{v}_{cm}(k) = \phi^T \times w \tag{6}$$

So, to get the non scaled compressor voltage the (7) should be applied:

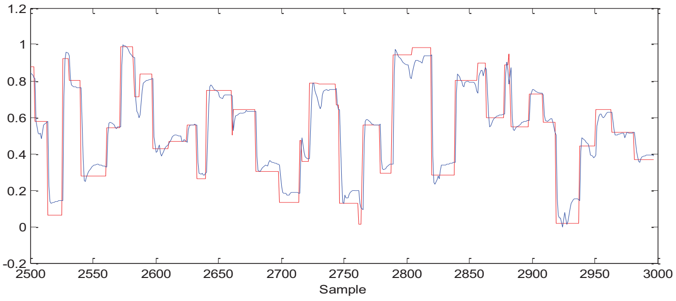

Figure 6. $v_{cm}$ Validation data for RBFNN model MAE (Mean Absolute Errors=0.0142)

$$v_{cm}(k) = \min v_{cm} + \hat{v}_{cm}(k) + \max v_{cm} - \min v_{cm}) \qquad (7)$$

On the other hand, to enhance the performance in steady state, the PID controller is added to form the feedback controller. In this case the activating compressor voltage is the sum of two controller outputs variables, one is from the RBF based feed-forward neural network controller, the other from the feedback PID controller. The current demand changing during the control is shown in Fig. 8. The following digital PID controller equation is used in [9]:

$$v_{cm\,2}(k) = y(k-1) + K_p\left[\left(1+\frac{T}{T_i}+\frac{T_d}{T}\right)e(k) - \left(1+\frac{2T_d}{T}\right)e(k-1) + \frac{Td}{T}e(k-2)\right] \quad (8)$$

After fine tuning, the PID controller that is used here with RBF based neural network controller for oxygen ratio regulation is

$$\hat{v}_{cm2}(k) = y(k-1) + 585e(k) - 45e(k-1)2.2\times10^{-4}e(k-2) \quad (9)$$

Here the sampling time is chosen to be 0.1sec. The measured oxygen ratio with time delay is the feedback signal of system.

### C. *Adaptive FF and FB Control Scheme*

The different of the strategy of adaptive RBFNN based FF control of oxygen ratio is the widths and the weights will be updated at each sample time. The RBF-NN based adaptive feed-forward and feedback control system structure is illustrated in Fig. 9. After training the RBFNN inverse model and we got satisfy good match. The PID controller is added to form the feedback control as discussed in the non-adaptive control.

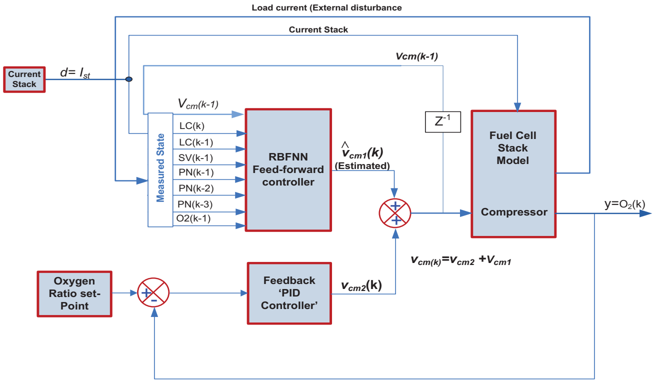

Figure 7. RBFNN FF and PID controller on the FCs

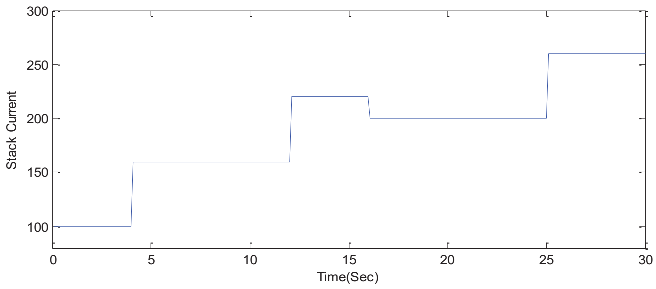

Figure 8. Fuel cell current demand changing during the control

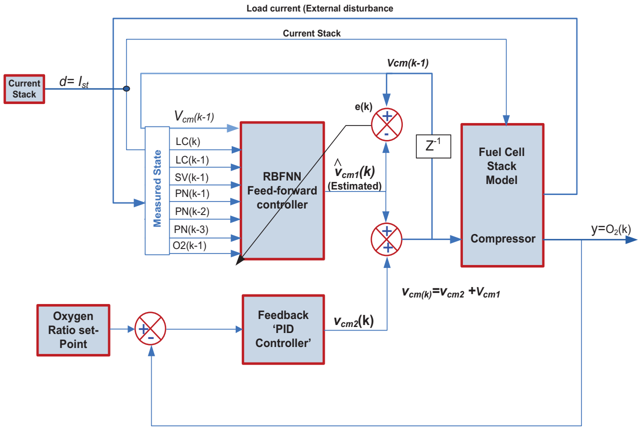

Figure 9. RBFNN FF and PID Controller on the Fuel Cell Stack

## IV. SIMULATION RESULTS

The output responses simulation of the oxygen ratio for non-adaptive and adaptive RBFNN feed-forward control for fuel cell stack are illustrated in fig. 10 and 11, the significant a difference can be seen between the performances of the two controllers. The tracking MAE of oxygen for non-adaptive and adaptive are 0.0045 and 0.0036 respectively.

### A. *Control Performance with 30% and 20% Reduction in the Compressor Gain*

The compressor is a machine to press the air inside the cathode but in some cases there are some problems associated with the compressor, which leads to reduce efficiency of the compressor.

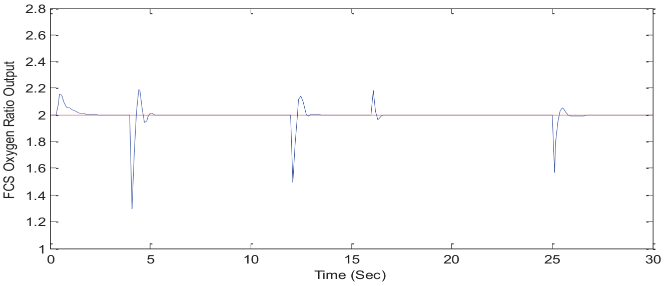

Figure 10. Simulation Result of Non-Adaptive RBF-Based FF & FB Control on FCS Oxygen Ratio

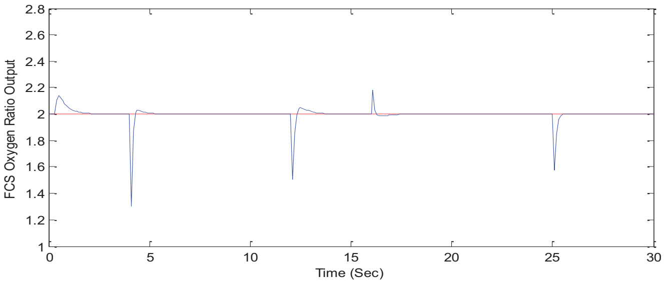

Figure 11. Simulation Result of Adaptive RBF-Based FF & FB Control on FCS Oxygen Ratio

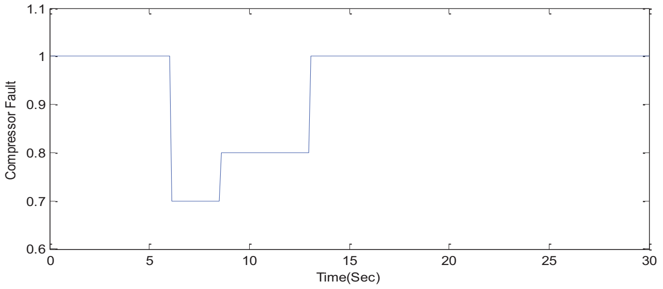

Figure 12. FCS Compressor Efficiency Fault Simulation

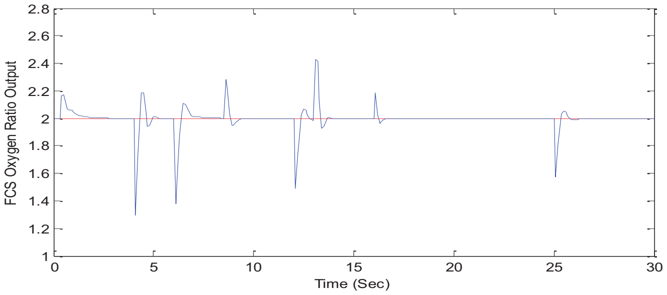

Figure 13. Simulation Result of Non-Adaptive FF and FB Controller on $O_2$ with 30~ 20% Reduction in Compressor Gain

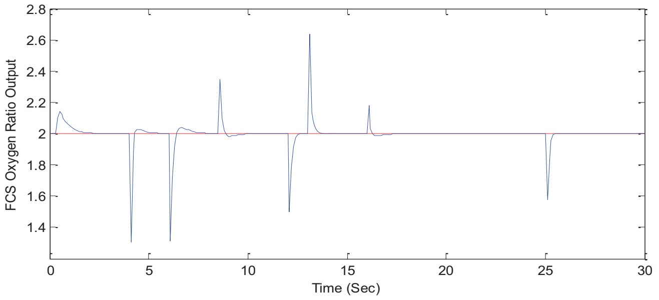

Figure 14. Simulation of Adaptive FF and FB Control on $O_2$ Ration With 30~20% Reduction In Compressor Gain

So, it needs regular maintenance because it contains gears and movement parts with oil circulation. When there is a problem in any part will affect on the efficiency of the compressor. The adaptive and non-adaptive RBFNN feed-forward controllers are evaluated with the current signal demand (Fig. 8) and the compressor gain reduction (Fig. 12). After reducing the compressor gain by 30% and 20% respectively, which will decrease the value of $O_2$ flow into the FCS port, the non-adaptive RBFNN model has a little capability to deal with this problem because it cannot retune itself according to this error, as a result it can't overcome this change and its MAE is 0.0083 (Fig. 13). However the adaptive RBF has the capability to retune itself to cope this situation and hence, achieves an improved control performance with a mean absolute error of 0.0075 (Fig. 14).

### B. *Control Performance with Compressor Gain Reduction and Manifold Leak*

Manifold leak is called component fault and to represent the air leakage fault, the manifold pressure equation in [6] is modified to (10):

$$\frac{dm_{sm}}{dt} = W_{cp} - W_{sm} - \Delta L \tag{10}$$

Where, $W_{cp}$ is the inlet mass flow (compressor flow), $W_{sm}$ is the supply manifold outlet mass flow and the added term $\Delta L$ is used to simulate the leakage from the supply air manifold, which decrease the air outflow from the manifold. $\Delta L = 0$ represents no air leak in the intake manifold. The air leakage level is simulated as 15% of total air intake in manifold as shown in Fig.15, and was simulated by changing the Simulink model of the FCS. From the oxygen ratio output shown in Fig. 16, the performance of non adaptive RBF FFC is acceptable and the MAE is 0.0126%. However, the performance of the adaptive RBF FFC as shown in Fig. 17 is better than the non adaptive. The adaptive RBF FFC can handle the manifold leak and therefore, achieves an improved control performance with mean MAE equal to 0.0090.

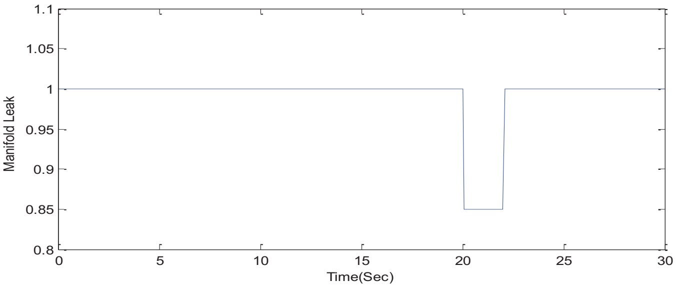

Figure 15. Manifold leak error simulate

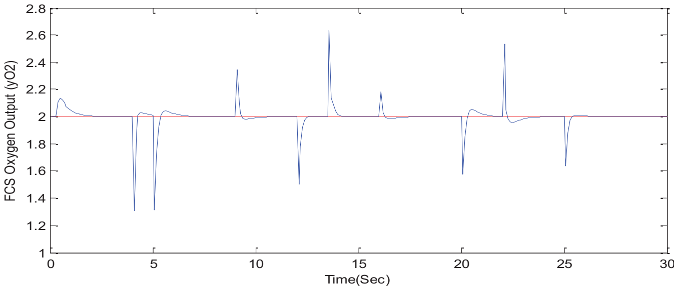

Figure 17. Oxygen ratio control result of the adaptive RBF FFC with compressor gain reduction and leak

TABLE III. EVALUATED

| Type of control method | Mean Absolute Error MAE |
|---|---|
| Non-adaptive RBFNN Control+PID controller | 0.0045 |
| Adaptive RBFNN +PID controller | 0.0036 |
| Non-adaptive RBFNN Control+PID controller with compressor gain reduction 30% and 20% | 0.0087 |
| Adaptive RBFNN Control+PID controller with compressor gain reduction 30% and 20% | 0.0075 |
| Non adaptive RBFNN Control+PID controller with compressor gain reduction 30% and 20% and the manifold leak 15% | 0.0126 |
| Adaptive RBFNN Control+PID controller with compressor gain reduction 30% and 20% and the manifold leak 15% | 0.0090 |

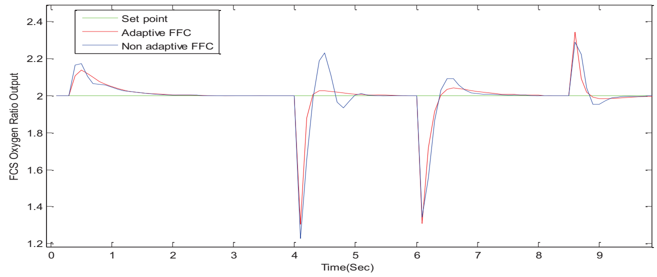

Figure 18. Comparing Adaptive and Non-Adaptive Control Performance when there is gain reduction

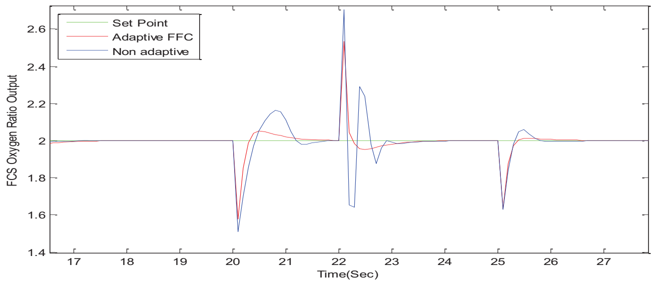

Figure 19. Comparing Adaptive and Non-Adaptive Control Performance when there are gain reduction and manifold leak

## V. DISCUSSION

From the Fig. 10 and 11 and the table III, when there is no reduction in the compressor gain, the RBFNN adaptive can give good performance than non-adaptive FFC with MAE equal to 0.0036 and 0.0045 respectively. However, reducing the compressor gain by 30% and 20% respectively, which will decrease the value of $O_2$ flow into the FCS port, the non-adaptive RBF controller has little capacity to deal with this situation because it was trained off-line and is fixed. As result it was unable to cope with an environment change see Fig. 13. However, the adaptive RBFNN can adjust the compressor voltage according to the real-time condition of the FCS and compensate for the influence of this system error after several sample times see Fig. 14. Fig. 18 show the comparison on oxygen ratio rates between Fig. 13 and 14. After that, the performance of the non adaptive and adaptive RBF FFC is evaluated with manifold leak Fig. 15 additional to current disturbance Fig. 8 and compressor gain reduction Fig. 12, the simulation results are as given in Fig. 16 and 17. The adaptive performance also, has more capacity to overcome the environmental change than the non adaptive because it was trained on-line according to the error see table III and Fig. 19.

## VI. CONCLUSION AND FUTURE WORK

This paper presents an adaptive and non-adaptive RBF control strategy to estimate the compressor voltage for fuel cell stack control to prevent fuel cell oxygen starvation and compressor surge during rapid load demands, gain reduction (30% and 20%) and manifold leak 15%. APID controller is used in the feedback to adjust the difference between the requested and the actual oxygen ratio by compensating the neural network inverse model output. When there is no reduction in the compressor gain the control strategy can adjust the compressor voltage of the fuel cell according to the current demand. From the other hand, when there is reduction (30% and 20%) in the compressor gain and 15% manifold leak. The non-adaptive RBF controller less ability than adaptive RBF controller because the adaptive was trained off-line, as a result it was unable to cope with an environmental changes. Furthermore, the adaptive RBFNN is able to adjust the compressor voltage to adapt to the real-time condition of the FCS and compensate for the influence of this system error after several sample times. The simulation results show the effectiveness of the adaptive control strategy.

*Abstract*—**The orthogonal Procrustes problem (OPP) deals with matrix approximations. The solution of this problem gives an orthogonal matrix to best transform one data matrix to another, in a Frobenius norm sense. In this work, we use semidefinite relaxation (SDR) to find the solutions of different OPP formulations. For the standard problem formulation, this approach yields an exact solution, i.e. no relaxation gap. We also address uncertainties in the data matrices and formulate a min-max robust problem. The robust problem, being non-convex, turns out to be a difficult optimization problem; however, it is relatively straight forward to approximate it into a convex optimization problem using SDR. Our preliminary results on robust problem show that the solution of the relaxed uncertain problem does not guarantee zero relaxation gap, and as a result, we cannot always find a solution, which satisfies the orthogonality constraint. In such cases we use orthogonalization, which gives the nearest orthogonal matrix from the SDR based solution. All these relaxed formulations, can be easily converted into a semidefinite program (SDP), for which polynomial time efficient algorithms exists. For the nominal problems, the presented approach may not be computationally efficient than other existing methods. In this work, our main contribution is to demonstrate that the SDR approach provides a unified framework to solve not only the standard OPP but can also solve the problems with uncertainties in the data matrices, which other existing approaches cannot handle.**

## I. INTRODUCTION

Orthogonal Procrustes problem (OPP) is a well known mathematical problem [1], [2]. It deals with finding a geometrical transformation that involves rotations or reflections with orthogonality constraint. In simple words, given two arbitrary real matrices $A$ and $B$ of the same dimension, OPP finds an orthogonal matrix $X$, which can best transform one matrix to the other, such that the Frobenius norm of the error $AX-B$ is minimized. There are many formulations of this problem, which can address rotations, reflections and translations having applications in various areas, such as image processing, computer vision, statistics, satellites and aerospace. In this work, we are mainly interested in the formulations, which can address rotations and reflections.

In image processing and machine learning, OPP is used in pose estimation, which involves estimation of a camera or some object position and orientation, either relative to a model reference frame, or at a previous time using a camera or a range sensor [3]. This application involves both rotation and translation. In satellites and aerospace applications, OPP is used for rigid body attitude determination and involve only rotations. In these applications, information of some vector quantities, such as the earth magnetic field, sun and star direction, object position, is obtained from both a sensor and a mathematical model to estimate the rigid body attitude. In statistics, OPP is used for principal component analysis, which is a mathematical procedure that uses an orthogonal transformation to convert a set of observations of possibly correlated variables into a set of values of linearly uncorrelated variables called principal components. For other variants of the Procrustes problems and their applications, please see [2].

Many solutions of the OPP exist in literature, suiting different applications. One mostly used solution of the orthogonal Procrustes problem is based on the singular values decomposition (SVD) [1], [4]. Different variants of the SVD based solutions are used in many applications. Few customized algorithms were also developed to meet some application specific requirements. For example, different solutions proposed for the Wahba problem [5], which is a subclass of OPP for rotations, and used in satellite attitude determination. Although, some proposed algorithms are based on the SVD approach [6], most of the algorithms used in practical applications are based on customized solutions for high computational speed, such as QUEST [7], ESOQ, ESOQ2 [8], [9].

Semidefinite relaxation (SDR) is considered a powerful and computationally efficient approximation technique for difficult optimization problems [10], such as non-convex and robust problems with quadratic cost and constraints. In this work, we demonstrate that this relaxation approach provides a unified framework to solve different formulations of the Procrustes problem and some of its more sophisticated extensions. We present SDR based convex formulations for the standard OPP and its variant for rotations, which needs to deal with the additional nonlinear constraint of $det(X)=1$. The relaxed formulations, however, result in no gap, giving an exact solution for the nominal problems. We also show that the SDR framework is much more general and can handle many extensions of this problem, which the other existing approaches cannot deal with. In this regard, our main contribution is to use the relaxation approach for the OPP with uncertain data matrices, which is a comparatively less addressed topic because of its

978-1-4673-1560-9/12/$31.00 ©2012 IEEE

mathematical complexity [11], [12]. We formulate and solve a relaxed version of the robust min-max problem. For the relaxed robust problem, the gap is not always zero. For such cases, we present a method to extract the nearest possible solution from the optimal, satisfying the constraints of the original problem.

The paper is organized as follows. In Section II, an orthogonal Procrustes problem is presented along with an existing solution based on the singular value decomposition. The application of the SDR is discussed in Section III, both for the standard problem and its extension for rotations. Section IV discusses the robust formulation and its solution. Section V presents numerical simulations to support the presented results and to show the effectiveness of the robust formulation.

*Notation:* For a matrix, $A \succ 0$ ($A \succeq 0$) means that $A$ is positive definite (semidefinite). The Frobenius norm of a matrix A is $\|A\|_F = \sqrt{\mathrm{tr}(A^TA)}$. $I_n$ denotes the identity matrix of size $n$, while $0_{n\times m}$ represents a matrix of $n$ rows and $m$ columns with all zero entries. The set of singular value (eigenvalue) of a $A$ is represented by $\sigma(A)$ ($\lambda(A)$). Operator $\mathrm{diag}(\lambda_1,\lambda_2,\dots,\lambda_n)$ represents a matrix of size $n\times n$, having only diagonal elements $\lambda_1,\lambda_2,\dots,\lambda_n$. Operator $\mathrm{trace}(A)$ is sum of all the diagonal entries of a matrix $A$.

## II. THE ORTHOGONAL PROCRUSTES PROBLEM

The orthogonal Procrustes problem (OPP) is mathematically defined as

$$\begin{aligned} \min_{X} \quad & \|AX-B\|_F^2 \\ \text{subject to} \quad & XX^T = I, \end{aligned} \tag{1}$$

where $A,B \in \mathbb{R}^{m\times n}$ are given data matrices, $m \geq n$ and $X \in \mathbb{R}^{n\times n}$ is the unknown orthogonal matrix, which belongs to an orthogonal group of order $n$, i.e. $\mathbb{X} =: \{X : XX^T = I, \det(X) = \pm 1\}$.

One important subclass of the orthogonal Procrustes problem includes an additional nonlinear constraint $\det(X) = +1$ (see, for example, Wahba problem [5]). This problem deals specifically with rotations and has a wide range of applications. In these applications, we are only interested in $X \in \mathbb{R}^{3\times 3}$ i.e. the solution now belongs to $SO(3)$, a special orthogonal group of order 3, defined as $\mathbb{X}_+ =: \{X : X \in \mathbb{R}^{3\times 3}, XX^T = I, \det(X) = +1\}$.

One can find many solutions of this problem in the literature. Most solutions are generally application specific, satisfying some special requirements, such as computational efficiency, numerical stability. We will present here one existing approach, which is considered numerically the most robust, and is based on the singular value decomposition (SVD) [1], [6].

### A. An SVD based solution

To find an SVD based solution, first we write the objective function of (1) as

$$\begin{aligned} \|AX-B\|_F^2 &= \mathrm{tr}\left((AX-B)(AX-B)^T\right) \\ &= \mathrm{tr}\left(AXX^TA^T + BB^T - AXB^T - BX^TA^T\right). \end{aligned} \tag{2}$$

To simplify the expression, we use the constraint $XX^T = I$ in (2) and write $AXX^TA^T = AA^T$. Further, neglecting the constant terms, i.e. $AA^T + BB^T$, we can write following maximization problem, which is equivalent to (1) in its argument.

$$\begin{aligned} \max_{X} \quad & \mathrm{tr}(BX^TA^T) \\ \text{subject to} \quad & XX^T = I. \end{aligned} \tag{3}$$

To solve this problem, we use the permutation property of the trace operator [16] and write the cost function as

$$\begin{aligned} \mathrm{tr}(BX^TA^T) &= \mathrm{tr}(X^TA^TB), \\ &= \mathrm{tr}(X^TU\Sigma V^T) \\ &= \mathrm{tr}(V^TX^TU\Sigma) \\ &\leq \mathrm{tr}(\Sigma) = \sum_i \sigma_i. \end{aligned} \tag{4}$$

Here $U\Sigma V^T$ is the singular value decomposition of the term $A^TB$, where $U,V$ are unitary matrices. The inequality in (4) becomes an equality when $V^TX^TU = I$, i.e. $X = UV^T$, which is the required solution.

For problems with additional constraint $\det(X) = +1$ (rotations), to maximize (4), we use few properties of the determinant operator [16] and write as

$$\begin{aligned} \det(V^TX^TU) &= \det(U^TVX) \\ &= \det(U^TV)\det(X) \\ &= \det(U^TV) = \pm 1. \end{aligned} \tag{5}$$

If $\det(U^TV) = 1$, the maximum is attained for $V^TX^TU = I$, while if $\det(U^TV) = -1$, the maximum is attained for $V^TX^TU = \mathrm{diag}(1,1,\dots,1,-1)$.

A unified solution for both problems can be given as

$$X = U\,\mathrm{diag}(1,1,\dots,\det(U^TV))V^T. \tag{6}$$

## III. A RELAXATION APPROACH FOR OPP

We addressed the orthogonal Procrustes problem (1) using semi-definite relaxation approach [12], [13]. We will present a relaxed formulation of the standard OPP (1) as well as the OPP for rotations.

### A. Relaxation of the standard OPP

To derive a semi-definite relaxation of the standard OPP, we use (2) and simplify the expression using the constraint $XX^T = I$. By introducing a linear objective, we can write the following optimization problem, which is equivalent to (1),

$$\begin{aligned} \min_{X,M} \quad & \mathrm{tr}(M) \\ \text{subject to} \quad & M - AA^T - BB^T + AXB^T + BX^TA^T \succeq 0, \\ & XX^T = I. \end{aligned} \tag{7}$$

As the orthogonality constraint $XX^T = I$ is not convex, we relax it to a convex quadratic inequality $XX^T \preceq I$. Using this relaxation, we write an approximate problem, which has a linear cost and linear matrix inequality constraints, as

$$\begin{aligned} \min_{X,M} \quad & \mathrm{tr}(M) \\ \text{subject to} \quad & \mathscr{M} \succeq 0, \\ & \mathscr{X} \succeq 0, \end{aligned} \tag{8}$$

where $\mathscr{M} = \begin{bmatrix} M + AXB^T + BX^TA^T & A & B \\ A^T & I & 0 \\ B^T & 0 & I \end{bmatrix}$ and $\mathscr{X} = \begin{bmatrix} I & X \\ X^T & I \end{bmatrix}$ are Schur complement [16] for the first and the relaxed second constraint in (7).

We have the following result regarding the gap between the original problem and its relaxation.

*Theorem 1:* There is no gap between problem (1) and its relaxation (8) and the SDR solution of (8) is the optimal solution of (1).

*Proof:* The proof is evident from (4). To elaborate this point, assume that the gap between (1) and (8) is zero, i.e. $\text{tr}(M) = AA^T + BB^T - 2BX^TA^T$. Now the minimum value of $\text{tr}(M)$ will be obtained when $BX^TA^T$ is maximum. From (4), we know that the maximum value of $BX^TA^T$ is achieved when $X = UV^T$, where $UV^T$ is the singular value decomposition of $A^TB$ and the obtained $X$ satisfies the orthogonality constraint. Hence, the solution of the SDR is obtained by pushing $XX^T$ towards $I$, resulting in no gap between (8) and (1). ■

### B. Relaxation of the OPP for rotations

The OPP formulation for rotations needs to handle the additional nonlinear constraint $\det(X) = 1$, which cannot be directly handled in the SDR framework. The OPP for rotations is of much interest from practical point of view for many applications. In such applications, we are only interested in the data matrices, where $n = 3$, e.g. applications such as finding camera orientation or rigid body attitude. In such cases, the rows of $A$ and $B$ represent information of same quantities obtained from different sources.

One approach to handle rotation problem in the SDP framework is proposed by [15]. We refer to [17, Proposition 4.1] for more details. We present the main point in a simplified form.

Consider a symmetric matrix $Z \in \mathbb{R}^{4\times 4}$, then an exact SDP representation of the convex hull of $SO(3)$ is given by the following expression, where the orthogonal matrix $X \in SO(3)$ is represented in terms of the elements of the matrix $Z$ as

$$X(Z) = \begin{bmatrix} z_{11}+z_{22}-z_{33}-z_{44} & 2z_{23}-2z_{14} & 2z_{24}+2z_{13} \\ 2z_{23}+2z_{14} & z_{11}-z_{22}+z_{33}-z_{44} & 2z_{34}-2z_{12} \\ 2z_{24}-2z_{13} & 2z_{34}+2z_{12} & z_{11}-z_{22}-z_{33}+z_{44} \end{bmatrix}, \tag{9}$$

if and only if the matrix $Z$ satisfies the following constraints

$$\begin{aligned} Z &\succeq 0, \\ \text{trace}(Z) &= 1. \end{aligned} \tag{10}$$

In the above expression $z_{ij} = Z(i,j)$. To understand this fact, consider that positive semidefinite $4\times 4$ matrices with both trace and rank 1 are given as

$$Z = \frac{1}{a^2+b^2+c^2+d^2}\begin{bmatrix} a^2 & ab & ac & ad \\ ab & b^2 & bc & bd \\ ac & bc & c^2 & cd \\ ad & bd & cd & d^2 \end{bmatrix}. \tag{11}$$

The image of this rank 1 matrix under the linear map (9) is precisely the group $SO(3)$ [17]. This parameterization is known as the *Cayley transform.*

Now embedding the trace constraint, i.e. $z_{11} + z_{22} + z_{33} + z_{44} = 1$ within the definition of $Z$, we can write an exact SDP representation for the rotation problem as

$$\begin{aligned} \min_{Z,M} \quad & \text{tr}(M) \\ \text{subject to} \quad & \mathscr{M} \succeq 0, \\ & Z \succeq 0, \end{aligned} \tag{12}$$

where

$$\mathscr{M} = \begin{bmatrix} M + AX(Z)B^T + BX(Z)^TA^T & A & B \\ A^T & I & 0 \\ B^T & 0 & I \end{bmatrix}. \tag{13}$$

The new $X(Z)$ with embedded trace constraint is given as

$$X(Z) = \begin{bmatrix} 2z_{11}+2z_{22}-1 & 2z_{23}-2z_{14} & 2z_{24}+2z_{13} \\ 2z_{23}+2z_{14} & 2z_{11}+2z_{33}-1 & 2z_{34}-2z_{12} \\ 2z_{24}-2z_{13} & 2z_{34}+2z_{12} & -2z_{22}-2z_{33}+1 \end{bmatrix}. \tag{14}$$

The solution of this problem gives $Z$ satisfying the constraints given in (10). This $Z$ is then used to calculate $X$, which is the optimal solution of the rotation problem. Later on, we will make use of this transformation to solve the rotation problem with data uncertainties.

## IV. THE OPP WITH DATA UNCERTAINTIES

Depending upon application, the data matrices $A$ and $B$ are generally obtained from different sources, e.g. some camera, sensors, mathematical models. This input information has always some sort of uncertainty, such as noise, sensor and modelling errors. The level of uncertainty, however depends upon the quality of measurement or mathematical modelling. In some applications the level of uncertainty can be high. It is a well known fact that these uncertainties can severely affect the accuracy of the obtained solution. The error in the solution will be large in the worst case uncertainties. To overcome the issue of sensitivity of the solution to data uncertainties, in this section, we will formulate and solve a robust optimization problem. In the formulated robust min-max problem, we obtain a solution, which could minimize the chosen cost function under the worst case uncertainties. The solution of the robust OPP gives better estimate of the unknown matrix $X$, with large data uncertainties.

### A. Uncertainty Representation in the Data Matrices

We consider the following data uncertainty structure:

$$\begin{bmatrix} \tilde{A} & \tilde{B} \end{bmatrix} = \begin{bmatrix} A & B \end{bmatrix} + E\Delta\begin{bmatrix} F_1 & F_2 \end{bmatrix}, \tag{15}$$

where $\tilde{A}$ and $\tilde{B}$ are uncertain data matrices, $A$ and $B$ represent the nominal data, $E, F_1$ and $F_2$ are known matrices and $\Delta$ is the uncertainty matrix such that $\Delta\Delta^T \preceq I$.

Perturbation model of this form is common in robust estimation, filtering and control [18], [19]. By a suitable selection of $E, F_1, F_2$ and $\Delta$, this model can represent both structured and unstructured uncertainty. For example, a norm-bounded full $\Delta$ will represent unstructured uncertainty, while a norm-bounded diagonal $\Delta$ with a suitable choice of other matrices will represent structured uncertainty. The suitable choice of $E, F_1$ and $F_2$ specify both the components of $A$ and $B$ affected by the uncertainty $\Delta$ and also the amount of uncertainty, e.g. as a percentage of input data.

In this work, we use this general uncertainty structure to formulate the robust problem. The choice of the constant matrices will define it to be structured or unstructured. Further, we will consider a ball uncertainty, i.e. $\Delta\Delta^T \preceq I$.

### *B. The Robust Problem*

For the robust problem formulation, we will follow the min-max approach, i.e. to minimize the objective function under the worst case uncertainties. Using the uncertainty model (15), we define the following robust problem:

$$\begin{aligned} \min_X \max_\Delta \quad & \|\tilde{A}X - \tilde{B}\|_F^2 \\ \text{subject to} \quad & XX^T = I, \\ & \Delta\Delta^T \preceq I, \end{aligned} \tag{16}$$

where $\tilde{A} = A + E\Delta F_1$ and $\tilde{B} = B + E\Delta F_2$.

To solve the min-max problem, we use SDR approach, following the same steps as used while solving the nominal problem (8). The main challenge here is to handle uncertainty in the max problem. By expanding the cost of (16), we get

$$\begin{aligned} J(X,\Delta) =& \|\tilde{A}X - \tilde{B}\|_F^2 \\ =& \operatorname{tr}((A+E\Delta F_1)XX^T(A+E\Delta F_1)^T - \\ & (A+E\Delta F_1)X(B+E\Delta F_2)^T - \\ & (B+E\Delta F_2)X^T(A+E\Delta F_1)^T + \\ & (B+E\Delta F_2)(B+E\Delta F_2)^T). \end{aligned} \tag{17}$$

The constraint $XX^T = I$ is used to further simplify the cost. To transform this problem into a tractable LMI formulation, we first replace the cost $J(X,\Delta)$ in (17) with a linear objective function trace$(M)$, and write the following equivalent problem

$$\begin{aligned} \min_{X,M,\Delta} \quad & \operatorname{tr}(M) \\ \text{subject to} \quad & M - J(X,\Delta) \succeq 0 \;\forall\; \Delta : \Delta\Delta^T \preceq I, \\ & XX^T = I. \end{aligned} \tag{18}$$

We can further simplify the optimization problem by relaxing the first constraint and making it independent of $\Delta$. For this we use following identity, where the left hand side is equal to the right hand side:

$$\begin{aligned} & M - J(X,\Delta) = \lambda E(I - \Delta\Delta^T)E^T + \\ & \begin{bmatrix} I & E\Delta \end{bmatrix} \begin{bmatrix} M - J_n(X) - \lambda EE^T & T_2(X) \\ (T_2(X))^T & \lambda I - J_\Delta(X) \end{bmatrix} \begin{bmatrix} I \\ \Delta^T E^T \end{bmatrix} \end{aligned} \tag{19}$$

where $J_n(X), T_2(X)$ and $J_\Delta(X)$ are defined as

$$\begin{aligned} J_n(X) &= AA^T + BB^T - AXB^T - BX^TA^T, \\ T_2(X) &= BX^TF_1^T + AXF_2^T - AF_1^T - BF_2^T, \\ J_\Delta(X) &= F_1F_1^T + F_2F_2^T - F_1XF_2^T - F_2X^TF_1^T. \end{aligned}$$

Further we define the matrix in the second term on right hand side of (19) as

$$\mathscr{T}(M,X,\lambda) = \begin{bmatrix} M - J_n(X) - \lambda EE^T & T_2(X) \\ (T_2(X))^T & \lambda I - J_\Delta(X) \end{bmatrix}. \tag{20}$$

The right hand side of (19) is either zero or positive because $(I - \Delta\Delta^T) \succeq 0$ and we impose $\lambda \geq 0$ and $\mathscr{T} \succeq 0$, ensuring that $M$ is an upper bound on $J(X,\Delta)$. Finally we write a relaxation of (16) as

$$\begin{aligned} \min_{X,M,\lambda} \quad & \operatorname{tr}(M) \\ \text{subject to} \quad & \mathscr{T}(M,X,\lambda) \succeq 0, \\ & \mathscr{X} \succeq 0, \\ & \lambda \geq 0, \end{aligned} \tag{21}$$

where $\mathscr{X}$ is the same as defined in (8).

*Remark 1:* Unlike Theorem 1, the gap between the robust problem (16) and its semidefinite relaxation (21) is not necessarily zero.

One possible reason of the non-zero gap may be that the relaxed maximization for all $\Delta : \Delta\Delta^T \preceq I$, is achieved at an $X$, which lies inside $XX^T = I$, i.e. the obtained $X$ does not satisfy the orthogonality constraint of the original problem.

### *C. Orthogonalization of X*

When the gap between the robust problem and its semidefinite relaxation is not zero, the $X$ does not satisfy the orthogonality constraint. For such cases, we find the nearest orthogonal $X$ in the Frobeneous norm sense. Such an $X$ can be obtained by solving following optimization problem:

$$\begin{aligned} \min_{X_o} \quad & \|X_o - X\|_F^2 \\ \text{subject to} \quad & X_oX_o^T = I, \end{aligned} \tag{22}$$

where $X_o$ is the required orthogonal matrix. This problem is same as the nominal Procrustes problem (1) with $A = I$ and $B = X$. The required matrix $X_o = U_xV_x^T$, where $U_x\Sigma_xV_x^T = X$ is the singular value decomposition of $X$.

### *D. Effect on the robust performance*

It can be argued that $X_o$ is not the optimal solution of (21), however it may be considered a suitable solution of (16), because this solution not only satisfies the orthogonality constraint and also results in a minimum cost variation. To evaluate this, let $e_1 = \tilde{A}X_o - \tilde{B}$ and $e_2 = \tilde{A}X - \tilde{B}$, then $\|e_1 - e_2\| = \|\tilde{A}(X_o - X)\| \leq \|\tilde{A}\|\|X_o - X\|$. A minimum value of $\|X_o - X\|$ will ensure that orthogonal $X_o$ will result in a minimum cost variation from the SDR solution. However, this new solution may not have the same properties from the robustness perspective. Some analysis of the performance is presented in the simulation section, however, the robustness properties of $X_o$ needs further analysis.

### *E. Robust problem for rotations*

Using the same transformation as discussed in Section III-B, we can write the robust problem (21) for rotations as

$$\begin{aligned} \min_{Z,M,\lambda} \quad & \mathrm{tr}(M) \\ \text{subject to} \quad & \mathscr{T}(M,Z,\lambda) \succeq 0, \\ & Z \succeq 0, \\ & \lambda \geq 0, \end{aligned} \tag{23}$$

where $\mathscr{T}(M,Z,\lambda)$ is the same as (20) with $X$ replaced by $X(Z)$.

However, it is observed that the proposed transformation also does not always work for problems with uncertainties in the data matrices. So for the cases where $X$ is not orthogonal, we still need to use orthogonalization as discussed above, to obtain a solution of the rotation problem.

Finally, based on the numerical simulations performed for the robust problem, we present following remark.

*Remark 2:* It is observed in the numerical simulations that limiting the size of the maximum uncertainty in the robust problem (21) can significantly reduce the number of cases, where the solution $X$ is not orthogonal. This observation also applies for rotation OPP (23), where the number of cases when $\mathrm{rank}(Z) \neq 1$, reduce significantly, reducing the likelihood of occurrence of the non-orthogonal $X$.

## V. Simulation Results

This section presents numerical simulations to evaluate the performance of the presented relaxation approaches and to support different discussions and results.

### *A. Analysis of the SDR for the standard OPP*

Firstly, we compare the solution of (8) with the SVD solution. For this comparison, we generate random $A$ and $B$ matrices of the size $10 \times 10$ using MATLAB command `randn`. Results of the simulation is given in Figure 1. The plot compares and cost $\|AX - B\|_F^2$ using both the SVD and the SDR based solutions. Gap between the relaxed and the original problem is also shown, which is zero, supporting Theorem 1. The last subplot shows $\det(X)$, which is $\pm 1$ indicating that the random problems are either rotations or reflections.

### *B. Analysis of the SDR for rotations OPP*

The performance of the OPP for rotations is shown in Figure 2. First subplot presents the relaxation gap, which is zero, validating the exactness of (12) for rotations. Other subplots show some other parameters of the $Z$ and $X$ matrices. It can be observed that the parameters, such as trace and rank of $Z$, and determinant of $X$ are as desired for all random cases.

### *C. Robust performance evaluation*

In this section, we evaluate the performance of the solutions obtained by solving the approximate formulations of the standard and the robust problems for a set of bounded uncertainties in the input matrices. For this analysis, we considered a structured uncertainty description with a suitable choice of $E, F_1$, and $F_2$ matrices. To obtained data for this test, first we generated a random $A$ matrix using MATLAB's `randn` command, and an orthogonal matrix $X$ using `orth` command, both in $\mathbb{R}^{3\times 3}$. Using this orthogonal matrix, we calculate the matrix $B$. This $A,B$ pair represents an exact data set, i.e. matrix $A$ can be exactly transformed to $B$ using $X$. In this pair, we added uniformly distributed random error within a range of 30% of the size of the elements of the true matrices, to obtain a data set with errors. We then solved both the nominal problem (4) and the robust problem (21). A large number of tests were performed by adding unifromly distrubuted random error in the nominal data within the set uncertainty bounds. The cost value was evaluated for both the nominal and the robust solution. The histogram of the test results is given in Figure 3, where $x-$axis represents the cost value, while $y-$axis represents the frequency of occurrance of the tests. It can be observed that the dispersion of the cost value using the nominal solution is much larger than the robust solution. This benefit is more obvious for the worst case scenarios. However, for nominal cases the robust solution suffers from an offset as compared to the nominal solution.

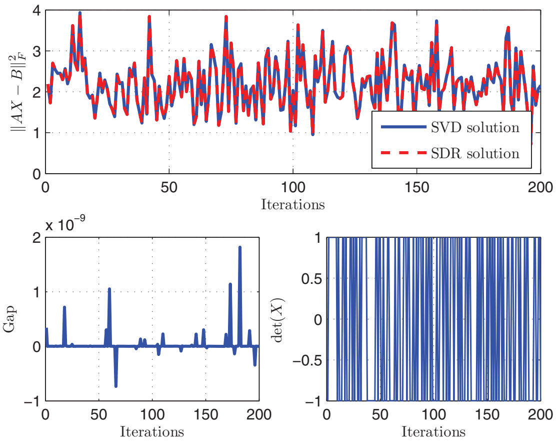

Fig. 1. Analysis of the semidefinite relaxation of the standard OPP (8).

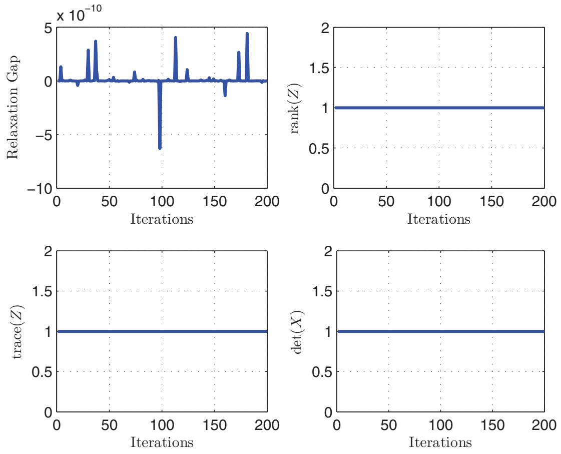

Fig. 2. Analysis of the semidefinite relaxation of OPP for rotations (12).

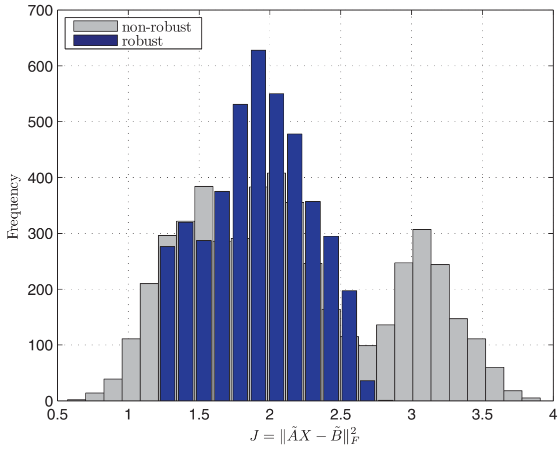

Fig. 3. Evalutation of the robust performance.

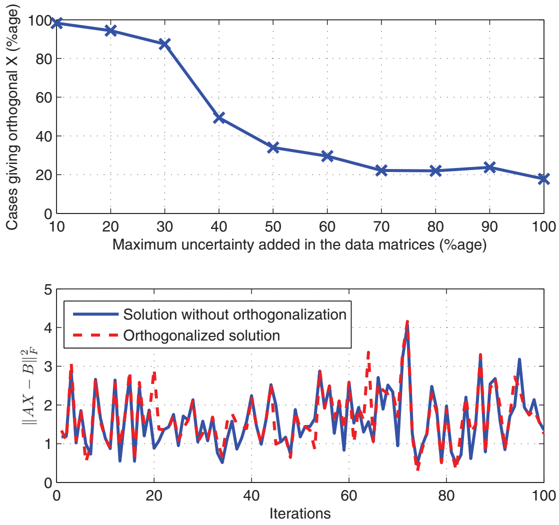

Fig. 4. First subplot shows number of orthogonal solutions (%age) verses uncertainty bounds, and second subplot compares cost using the SDR solution before and after orthogonalization.

### D. Orthogonalization step

Lastly, we analyze the orthogonalization step and its effects on the cost value. For the first point, we performed simulations by varying maximum uncertainty level in the the nominal data and plotted the number of cases (in percentage), which give an orthogonal $X$. Results are shown in the first subplot of Figure 4. The analysis shows that the number of tests having orthogonal $X$ increase significantly, when the size of the uncertainty is small, supporting Remark 2. Further, we compare the cost variation using the optimal solution of the approximate robust problem (21) and its orthogonalized solution for 200 runs of random data with within bounded uncertainty, showing that the cost variation due to the orthogonalization is not much.

## VI. Conclusions and Future Work

We presented an approach based on semidefinite relaxations to solve different formulations of the orthogonal Procrustes problem. It was demonstrated that the relaxation of the nominal problem results in no gap between the actual and the relaxed problems. The SDR framework also allows to handle uncertainties in the data matrices. It was further demonstrated that while considering uncertainties, the gap is not necessarily zero, which results in a solution not satisfying the orthogonality constraint of the original problem. In such cases, orthogonalization was proposed for the obtained solution. However, there are some issues, which need further analysis. In this regard, our future work may consider further study of the relaxation gap with uncertainties. Moreover, some work may be done on casting these problems in a standard SDP framework and analyzing its computational complexity using some efficient SDP algorithm.

*Abstract*—**Climate change concerns, increasing global energy demand, coupled with limited supply of fossil fuels, calls for development of new power source. Solar energy is a very promising renewable energy source to moderate the growth of energy demand. The combination of electrolyser and fuel cell which use hydrogen as an energy carrier extends the utilisation of the solar energy. For this integrated solar powered hydrogen production, storage and utilisation system, one of the problems is to develop an efficient control system to improve the performance of the overall system. This paper presents a power management strategy based on fuzzy logic technology to address such problem. The target of this power management strategy is to meet the power demand, to maximise the hydrogen production and to minimise the usage of battery. Therefore, the overall system's efficiency will be increased and lifetime of the battery pack will be extended. The numerical results based on real solar data for a one year period shown that the proposed fuzzy logic controller behaved as expected, it was able to meet the power demand and to store the hydrogen when possible while maintain the battery's state of charge at desired level.**

***Keywords - Hydrogen production and storage, Renewable energy, Power management, Fuzzy logic control***

## I. Introduction

The global energy demand is increasing rapidly. The concerns of limited supply of conventional fossil fuels and the emission of green house gases call for new solutions to this energy problem. Renewable energy can be part of the solution to provide clean and sustainable energy supply.

However, the inherent intermittency in most of the renewable sources causes problems for power-on-demand requirements. Hydrogen is considered to be a promising candidate as an energy carrier to compensate this problem.

Renewable powered hydrogen production and utilisation systems can be either standalone or grid connected. Over the past few years, the development and application of such systems has increased significantly. A large body of research work addressed various topics for such systems, including modelling, simulation, control and performance evaluation [1]–[7].

A typical system normally consists of one or several renewable power sources, such as photovoltaic (PV) array, wind turbines, micro-hydro, geothermal, etc. An electrolyser is used to convert excess energy to produce hydrogen as an energy carrier. The fuel cell will be used as power source to convert the chemical energy from hydrogen into electrical energy when the power demand is higher than the supply of renewable sources. Batteries or a battery pack are usually used to maintain a constant DC bus voltage and to store or supply short-term energy. The emphasis of such systems is not only to improve the performance of existing hydrogen production, storage and utilization technologies, but also to integrate various units effectively with renewable energy sources through overall power management strategies [8].

Several researchers addressed power management strategy (PMS) design and applications for such system. However, from above examples [1]–[6], [9], [10], it can be seen that for most of the reported PMS, the state of charge (SOC) level of the battery is the main parameter that governs the operation sequence of the electrolyser and the fuel cell. The start-up and shut-down of the electrolyser and fuel cell is relied on the fixed SOC limits. Reference [11] indicated that the two important shortcomings for this type of algorithm are:

1) it did not take into consideration of the system's state except for the batteries' SOC;
2) it did not allow the control of the production or consumption of the hydrogen, which would help manage the energy in the system.

The fuzzy logic (FL) controller developed by [11] determines the appropriate hydrogen production/consumption rate as a function of the system's power inputs and outputs and the batteries' SOC. However, the authors in [11] have not considered the system sizing that may lead to significant drop of hydrogen storage level in 7-day period. Meanwhile, although the battery SOC was maintained within a reasonable region (i.e., between 40% and 60% as the results demonstrated), the oscillation means that considerable amount of energy may be wasted during charging and discharging process of the battery pack.

This study focuses on developing PMS based on FL control methodology for solar powered hydrogen production, storage and utilisation system to improve the overall system's efficiency. The purpose of proposed FL controller is twofold, one is to maximise the hydrogen production which is a function

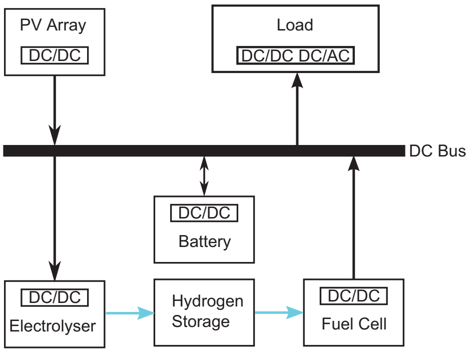

Fig. 1. System configuration of the solar powered hydrogen production, storage and utilisation system

of the battery SOC and the difference of the power flow between available solar power and load demand, the other one is to minimise the usage of batteries. The entire system is modelled with consideration of system sizing and systematic modelling approach. Then the FL controller is designed in order to achieve aforementioned control objectives. Finally, performance of the overall control system is validated over a one-year period using real solar data. The numerical results shown that the designed system has the capability to satisfy the daily load demand as well as produce hydrogen using excessive solar power for future usage, storage, transportation or hydrogen powered car refuelling.

## II. System configuration

The structure of this standalone system is shown in Fig. 1 where the black arrow represents the electricity flow and the blue arrow represents the hydrogen flow.

In this study, a photovoltaic array is considered as the main power source to the system to meet the predefined load demand. Due to the inherent intermittent nature of solar power, a battery pack is included only to smooth the fluctuation of the solar power if necessary. When excess power is available, hydrogen will be produced using an electrolyser. When a power shortage occurs, a fuel cell will be used to convert the chemical energy from hydrogen to electric energy.

The complete model is developed in order to represent the physical system and to design and validate the performance of the proposed controller. The detailed model of DC/DC or DC/AC converter is neglected and they are treated as an ideal device to produce power which is determined by the FL controller.

### A. Load profile

The purpose of this solar hydrogen system is to use solar power to satisfy the load demand of the office block of Hydrogen Centre of University of Glamorgan at Baglan Energy Park, Port Talbot, United Kingdom and utilise excess power to produce hydrogen for later use, storage, transportation or for fuel cell car refuelling, therefore, the load profile analysis is essential for determine the size and the control design of the overall system.

| Appliance | Power (W) | Duty cycle (hours) | Energy consumption (Wh) |
|---|---|---|---|
| Fridge | 23 | 24 | 552 |
| Microwave | 700 | 0.3 | 210 |
| Kettle | 3000 | 0.4 | 600 |
| Lighting | 400 | 4 | 1600 |
| Laptops | 390 | 8 | 3120 |
| Auxiliary devices | 1200 | 24 | 28800 |
| Total | 5713 | – | 34882 |

TABLE I
List of appliances' power, duty cycle and energy consumption

The average energy consumption $E_{load}$ can be estimated by equation

$$E_{load} = \sum_{i=1}^{n} I_{load} V_{load} D_{load} \tag{1}$$

where $I_{load}$, $V_{load}$, $D_{load}$ are the current, voltage and duty cycle of each appliance used in one day, respectively. $n$ is the number of the appliances.

The considered office block is utilised between 09:00 and 17:00 and includes 6 laptops, 1 mini refrigerator, 1 microwave, 1 kettle, lighting and several auxiliary devices such as security system, monitor system, phone system, LAN, boiler etc. The list of appliances together with their power, duty cycle is given in Table I. It is reasonable to assume that this daily load will keep constant throughout the year, for weekdays.

### B. Battery model

The battery stack creates a linkage between all components in the solar powered hydrogen system, it is used as an energy buffer to compensate the power fluctuation.

The battery state of charge $S$ is the only state variable of the battery system model and is given by

$$S = \frac{\left(Q_{max} - \int_0^t I_b dt\right)}{Q_{max}} \tag{2}$$

where $Q_{max}$ is the battery's maximum capacity [12].

The battery current $I_b$ is defined by

$$I_b = -(I_{pv} - I_{load} - I_{el} + I_{fc}) \tag{3}$$

where $I_{pv}$ is the PV array's current, $I_{load}$ is the load current, $I_{el}$ is the electrolyser current and $I_{fc}$ is the fuel cell current.

When charging the battery, the current is negative and positive current indicates discharging mode of the battery. It is found that in order to lengthen the battery lifetime, overcharging and deep discharging should be avoided.

### C. Electrolyser model

The electrolyser operating current is defined by

$$I_{el} = \frac{P_{el}}{V_{el}} \tag{4}$$

where $P_{el}$ is the power of electrolyser.

| | |
|---|---|
| $f_1$ | 269.9112 |
| $f_2$ | 1.1013 |
| $r_1$ | $9.2434 \times 10^{-5}$ |
| $r_2$ | $-2.2120 \times 10^{-7}$ |
| $s$ | 0.1084 |
| $t_1$ | $-1.0636$ |
| $t_2$ | 8.7077 |
| $t_3$ | 267.7084 |
| $A$ | 0.013 |
| $n_c$ | 48 |

TABLE II
PARAMETERS FOR THE ELECTROLYSER

For a given cell temperature, the operating voltage of the electrolyser is expressed as

$$V_{el} = V_{rev} + \frac{r_1 + r_2 T}{A} I_{el} + slog\left(-\frac{t_1 + t_2/T + t_3/T^2}{A} I_{el} + 1\right) \tag{5}$$

where $V_{rev}$ is the reversible cell voltage, $r_1$, $r_2$, $t_1$, $t_2$, $t_3$ are parameters which can be determined experimentally [13].

The hydrogen production rate is proportional to the electrolyser current, hence, the total hydrogen production for an electrolyser which consists of several series connected cells, can be expressed as

$$\dot{n}_{H_2} = \eta_F \frac{n_c I_{el}}{2F} \tag{6}$$

where $\eta_F$ is the Faraday efficiency and can be calculated as $\eta_F = \frac{(I_{el}/A)^2}{f_1 + (I_{el}/A)^2} f_2$, $n_c$ is the number of series connected cells, $F$ is the Faraday constant.

The validated parameters used in the electrolyser model are listed in Table II.

### D. Fuel cell model

The fuel cell operating current is defined as

$$I_{fc} = \frac{P_{fc}}{V_{fc}} \tag{7}$$

where $P_{fc}$ is the fuel cell power.

The fuel cell model is derived and validated in [14]. A brief detail of the fuel cell model is described here, detailed information can be found in [14]. The fuel cell stack voltage can be calculated by multiplying the cell voltage by the number of cells $n_{fc}$ of the stack, hence

$$V_{fc} = n_{fc} \times (E - V_{act} - V_{ohm} - V_{con}) \tag{8}$$

where

$$E = \frac{1}{2F}\left\{\Delta G + \Delta S(T - T_r) + RT\left(ln(P_{H_2}) + \frac{1}{2}ln(P_{O_2})\right)\right\} \tag{9}$$

where $E$ is the open circuit voltage of the fuel cell, $\Delta G$ is the change in the free Gibbs energy, $\Delta S$ is the change of the entropy, $R$ is the universal constant of the gases, $P_{H_2}$ and $P_{O_2}$ are the partial pressures of hydrogen and oxygen respectively. $V_{act}$ represented the activation over potential at the electrodes; $V_{ohm}$ represents the ohmic over potential caused by electrical and ionic conduction loss; $V_{con}$ represented the concentration over potential caused by mass transport limitations of the reactants to the electrodes.

The activation over potential $V_{act}$, including anode and cathode can be calculated as

$$V_{act} = -\left\{\xi_1 + \xi_2 T + \xi_3 Tln\left(\frac{P_{O_2}}{5.1 \times 10^6 e^{\frac{-498}{T}}}\right) + \xi_4 Tln(I_{fc})\right\} \tag{10}$$

$\xi$ represents parametric coefficient for the cell model.

The ohmic voltage drop $V_{ohm}$ is determined by the following expression

$$V_{ohm} = I_{fc}\left(\rho_m t_m A_{fc}^{-1} + c\right) \tag{11}$$

In this model a general expression for resistance is defined to include all the important parameters of the membrane. The resistance to the transfer of protons through the membrane is assumed to be a constant ($c$) and included in the equation as an additional term. $\rho_m$ is the specific resistivity of the membrane for the electron flow. $t_m$ is the thickness of the membrane, $A_fc$ is the cell active area.

The voltage drop due to the mass transport can be determined by

$$V_{con} = -Bln(1 - \theta) \tag{12}$$

and

$$\theta = \left(I_{fc} A_{fc}^{-1}\right)\left(\left(I_{fc} A_{fc}^{-1}\right)_{max}\right)^{-1} \tag{13}$$

where $B$ is a parametric coefficient that depends on the cell and its operation state.

The hydrogen consumption rate of the fuel cell stack is given by

$$\dot{n}_{fc} = \frac{n_{fc} I_{fc}}{2F} \tag{14}$$

## III. FUZZY LOGIC BASED POWER MANAGEMENT STRATEGY

### A. Control objects

The control object is to make full use of the solar power to maximise the hydrogen production and minimise the usage of battery stack, i.e., keep the battery SOC between 50 -60% which will extend its lifespan and increase the overall system's efficiency.

The operating strategies for power management system are listed as follows:

1) The highest priority is to utilise the solar power to satisfy the predefined power demand.
2) If excess solar energy is available, it will be sent to the electrolyser to generate hydrogen for future usage.
3) The electrolyser will keep running as long as the addition power from PV array is available. The electrolyser

maximum power is set to 16kW. The addition power transferred from PV array to the electrolyser will not exceed this limit.

4) If there is still additional power generated by PV array when the load demand is satisfied and the electrolyser is running at its peak limit, extra power will be utilised to charged the battery if the battery SOC is low.
5) Dumping power is only required if the electrolyser is running at its maximum power level and the battery SOC is at desired level.
6) If the power generated by PV array is insufficient to support the electrical demand, the difference is supplied by fuel cell stack which can run up to 4kW.
7) Only when the power demand is higher than the power supply of PV/FC combination, will the battery be used to provide short-term compensation.

### B. Fuzzy logic controller

The required control objects are implemented by a two-input-one-output fuzzy logic controller. Two inputs to the controller are the difference power flow ($dP$) and the battery's SOC. The difference power flow indicates the difference between available solar power and the power demand. The controller will use this information to decide whether excess solar power is available for hydrogen production. The SOC is used to maintain the battery's SOC at desired level in order to prevent overcharge / deep discharge of the battery.

The fuzzy mechanism consists of triangular membership functions for the two inputs and for the output is shown in Fig. 2 and Fig. 3 respectively. The reason for choosing triangular membership function is mainly for the simpler computation of membership value. The dP flow is divided into eight variables. Negative power supply means fuel cell or battery is required to supply the difference and positive power means addition solar power can be used to produce hydrogen or charge the battery. The battery SOC is also described by three variables. It is desired that the SOC will be maintained within the region between 50-60%. Negative power output means fuel cell power is required to compensate the power shortage and positive power output indicates that excess solar power is available for electrolyser to produce hydrogen.

The rules of the FL controller are demonstrated in Table III and the definitions of the linguistic variables are described in Table IV. In Table III, the top row of the table shows the difference of power flow ($dP$) and the left column is the battery's SOC. The cells of the table at the intersection of rows and columns contain the linguistic value for the output corresponding to the value of the first input written at the beginning of the row and to the value of the second input written on the top of the column. The rule output was defuzzified using a centroid computation.

## IV. Simulation and results

The model of the aforementioned solar hydrogen system is created in MATLAB/Simulink and the proposed fuzzy logic controller is implemented using the Fuzzy Logic Toolbox. The

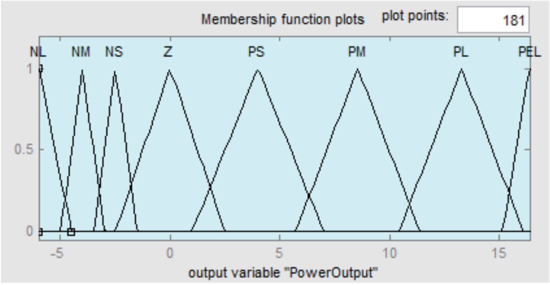

Fig. 3. Membership function for output variable

purpose of the simulation is to observe the performance of proposed system over a period of year including day and night.

The real solar data gathered from the PV panel for entire year of 2010 is utilised in this analysis. The PV array is rated at 18kWp. The annual solar power delivered by the PV array is illustrated in Figure 4. The fluctuation of delivered solar power can be seen from the figure. In summer, the maximum power solar panel can deliver can reach up to 18kW, while during winter and early spring, this value can drop down lower than 0.1kW.

The power generated by the PV array will be used to satisfy the user power demand as stated previously and the difference between available power and the load demand is shown in Figure 5. The negative power indicates that there is insufficient solar power to meet the power demand therefore fuel cell is required to supply the difference. The positive region means that excess solar power is available and can be utilised by electrolyser to produce hydrogen. The figure demonstrated that during winter and spring season, from November to April, due to low solar irradiation and short daylight, the power generated by solar array cannot satisfy the load demand, therefore, the fuel cell has to operate for most of the time to compensate this power shortage. During summer season, the frequency of fuel cell usage is reduced and the electrolyser is running more frequently to convert solar power into hydrogen.

Under the control of the proposed fuzzy logic controller, the hydrogen production rate is shown in Figure 6. The hydrogen consumed by the fuel cell is shown in Figure 7. A more clear demonstration of monthly hydrogen production by electrolyser, hydrogen consumption by fuel cell and the net hydrogen in storage overall this test period are shown in Figure 8. The results fit the seasonal profile demonstrated in the previous figures very well and clearly indicate that by using such system, the load demand can be satisfied and there is an abundance of hydrogen produced which can be used for storage, transportation or fuel cell refuelling.

Figure 9 shows the SOC of battery stack. The initial SOC was set at 50%. From the figure it can be seen that the proposed FL controller can maintain the battery's SOC around 55% during the entire year as desired, which increases the efficiency of overall system and prevents abusive use of the battery and hence contributes to extend the lifespan of the battery pack.

## V. Conclusion

This paper presented a solar powered hydrogen production, storage and utilisation system. The system uses solar power as a main power source to meet the power demand, and utilises hydrogen as an energy vector to store excess solar power via electrolyser. When required, the produced hydrogen will be converted back to electric energy using fuel cell. The proposed FL controller determines the time to produce hydrogen and to convert it back to electricity. The purpose of the FL controller is to maximise the hydrogen production and minimise the usage of the battery stack to increase the system's efficiency and to extend the lifetime of the battery stack.

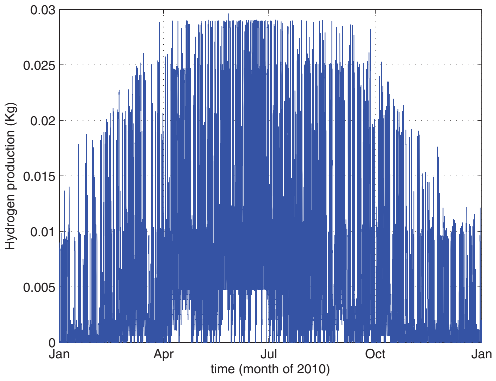

Fig. 6. Electrolyser $H_2$ production rate

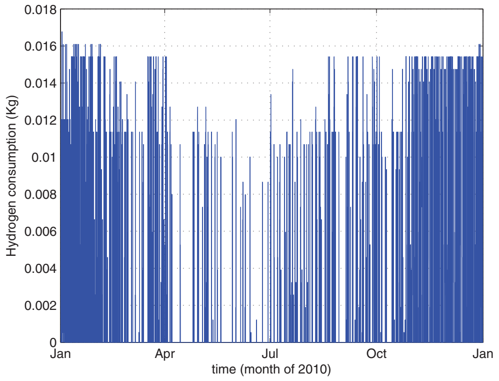

Fig. 7. Fuel cell $H_2$ consumption rate

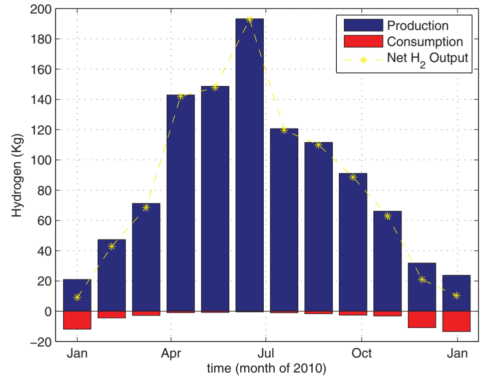

Fig. 8. Monthly variation of hydrogen production, consumption and net hydrogen output

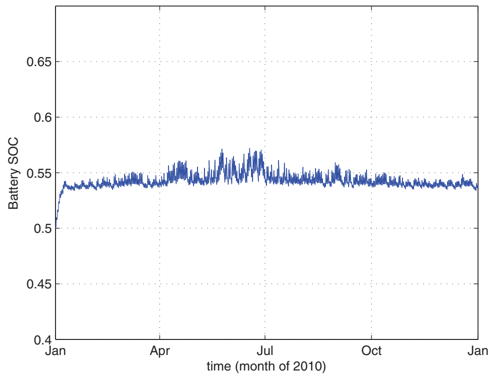

Fig. 9. SOC for entire year

The proposed system is simulated for a complete year with real solar data gathered from University of Glamorgan Hydrogen Centre. The purpose of the simulation is to evaluate the performance of the proposed controller. The numerical results shown that the proposed controller behaved as expected, it was able to satisfy the power demand and to store the hydrogen when possible while maintain the battery's SOC at desired level.

*Abstract*—**the paper is to investigate dynamic responses of supercritical power plants (SCPP) and study the potential strategies for improvement of their responses for Grid Code compliance. An approximate mathematical model that reflects the main features of SCPP is developed. The model unknown parameters are identified using Genetic Algorithms (GA) and the model is validated over a wide operating range. A model based predictive control (MPC) is then proposed to speed up the dynamic responses of the power plant by adjusting the reference of the plant local controls instead of direct control signal applications. Simulation results have shown encouraging improvement in performance of the plant with no interference with its associated local controllers.**

## I. INTRODUCTION

It is well known that the Supercritical (SC) power plant is a complex process and has a large thermal inertia. Due to its once-through boiler structure, there are concerns for its dynamic response speed as there is no drum to buffer energy in the system and also there are concerns in Grid Code compliance ([1]). The first attempt towards optimal control of oil-fired SC power plants was reported in 1978 [2] with a state space model for identification and control optimization using a dynamic programming technique. Nonlinear model based predictive control (NMBPC) was reported in [3] using a reduced order physical system model to predict the next step control values. Dynamic matrix control (DMC) was published in [4] designed for SC power plants using linear model identified from step response tests. In [5], a model of an existing SC once-through power plant was reported for simulation study of plant frequency responses. The recurrent neural network modeling and modified predictive optimal control approach for coal fired SC and ultra-supercritical (USC) power plants were reported in [6] [7][8]. The paper is to study the control strategy by taking prompt actions in mill control to speed up the whole process dynamic responses.

The main contributions of the paper are: 1) a nonlinear vertical spindle mill model representing the whole milling process is integrated to a SC power plant model, which is developed by the research group at Warwick and Birmingham Universities in collaboration with the industrial partners. This has improved the whole SC power plant (SCPP) model as the previous SCPP mathematical models generally assume instantaneous response from the fuel source. In the paper, the influences of milling process capability and mill control to the whole power plant dynamic responses are investigated. 2) The paper proposed a Model Predictive Control (MPC) method to provide the updated optimal demand/set point values for the coal flow, feed water flow and the main steam valve position reference. Then those values are fed to the mill, boiler and turbine local controllers. If the amount of desired coal flow is optimally predicted in advance, there will be more stored coal in the mills to give quicker responses. The study has indicated that the proposed MPC strategy for adjusting the reference values of the plant local controls plays an important role in improving the whole plant dynamic response speeds.

## II. SC POWER PLANT DESCRIPTION AND ITS MATHEMATICAL MODEL

Vertical spindle mills are the dominant types used for SC coal fired power plants ([9-10]). The raw coal enters the mill inlet tube and carries the coal to the middle of grinding rotating table. Hot primary air flows into the mill from the bottom to carry the coal output from grinding process to the classifier that is a multi-stage separator located at the top of the mill. The heavier coal particles fall down for further grinding and the pulverized coal is carried pneumatically to the furnace. Inside the boiler, the chemical energy released from combustion is converted to thermal energy. The heat is exchanged between the hot flue gas to the water through heat exchangers. The boiler contains thin tubes as heating surfaces which form the economizers (ECON), waterwall (WW), low temperature superheater (LSH), platen superheater (PSH), final stage superheater (FSH), and reheaters (RH). The water is forced at high pressure (SC pressure) inside the economizer and passes through all those heating sections. Since pressure is above the critical point, the sub-cooled water in the economizers converted to the supercritical steam in the superheaters without evaporation. The SC steam is then expanded through turbines. The high pressure (HP) turbine is energized by the steam supplied at final stage superheater and the reheaters are used to reheat the exhausted low pressure steam from the HP turbine before it returns to the IP turbine. The mechanical power is converted to electrical power by synchronous generator coupled to the turbines. In the work described in the paper, a 600MW SC power plant is selected with the boiler specifications at boiler maximum continuous rating (BMCR) shown in Table I

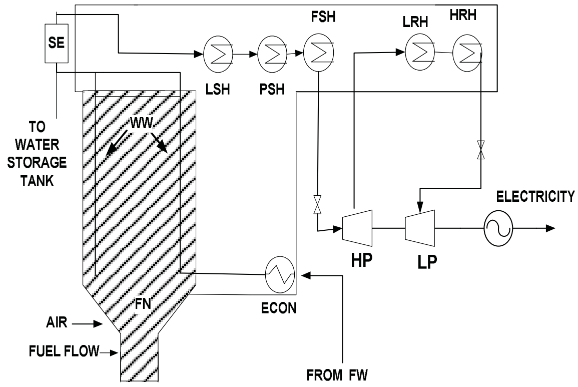

Fig.1 Schematic view of the SCPP under investigation

TABLE I. BOILER SPECIFICATION

| | |
|---|---|
| Flow rate of superheated steam(t/h) | 1780 |
| Steam pressure (MPa) | |
| FSH outlet | 25.4 |
| ECON inlet | 27.6 |
| steam temperature (C°) | |
| FSH outlet | 570 |
| ECON inlet | 288 |
| Fuel (t/h) | Pulverized coal of 276 |

For the purpose of dynamic simulation studies and control system development, a nonlinear mathematical model with 20 differential equations for supercritical boiler-turbine-generator systems, rooted from physical principles, has been developed and integrated with a vertical spindle mill model [9]. Some assumptions are made to simplify the model structures which are:

- Fluid properties are uniform at any cross section, and the fluid flow in the boiler tubes is one-phase flow.
- In the heat exchanger, the pipes for each heat exchanger are lumped together to form one pipe.
- Only one control volume is considered in the waterwall.
- The dynamic behavior of the air and gas pressure is neglected.
- Only the change in internal energy is considered, the deviations or changes of kinetic energy and potential energy of fluid are neglected.

Due to page limitation, only a brief description of the model is given in the paper, the detailed procedures for the model derivation and parameter identification are reported in our work [10][11]. The boiler model is developed by deriving the nonlinear dynamics of pressure and temperature in each heat exchanger from mass and energy balance equations of a certain control volume. Those equations are strongly coupled by the equations of SC steam flow and heat flow in the boiler. The heat flow is directly related to the fuel through constant gains and fuel calorific value. It should be noted that major boiler model parameters are either calculated from steam tables or identified using the data from certain operating unit responses. The former method is more suitable for steady state system model so the latter approach has been adopted with the real power plant measured data. The turbines HP and IP are modeled by the same principles of energy conservation and simply linked to the outlet of RH and FSH outlets of the boiler. The generator nonlinear model [12] has been coupled to the turbine model through torque equilibrium with other algebraic equations. The model has two direct inputs of feedwater flow and fuel flow and one indirect input which is the valve position reference. The model equations have been implemented by MATLAB/SIMULINK so that the output scope can be easily accessed at any point in the model. The computer graphical implementation includes gains, integrators, differentiators, transfer functions in s domain, summing points, multiplication points...etc. Furthermore, Matlab stiff function (ode15s) solver has been used for numerical solution of the model during identification or verification simulations. Fig.2 shows the model blocks diagram with all combined subsystems and the symbols are listed in Table.II. The procedure of parameter identification is summarized in the next section.

## III. PARAMETER IDENTIFICATION

It is worth noticing that the physical model parameters are not known precisely. As described in the previous section, the GA optimization technique was adopted to identify the model unknown parameters. It should be mentioned that GA is robust optimization technique that is suitable for nonlinear system identification. Unlike conventional mathematical optimization methods, GA technique is able to tune all model parameters simultaneously with multi-objective optimization. Furthermore, GA produces global optimal solution for complex systems or functions because of parallel distributed search mechanism and mutation. The identification scheme is graphically represented in Fig.3. The work employed the coal mill model reported in [9] and the mill parameters are given in the reference. The rest of the plant model parameters are identified according to measured data responses of: 1) main steam temperature; 2) main steam pressure; 3) reheater pressure; 4) SC steam flow rate. The measured variable data for identification of turbine /generator parameter optimization are: 1) mechanical power; 2) electrical power; 3) system frequency. The onsite measurement data from a 600MW SC power plant is used for identification. Data set.1 has been used for identification which represents an increase in the load demand from 35% to 100% of load demand. Data sets 2, 3 and 4 are used for further model investigations. Fig.4 represents identification result while figs 5, 6, 7 show some verification results for different sets of data. It can be seen that the mathematical model reflects the main variation trends of the real power plant measurements over wide operating range although some assumption for simplifications were initially made.

## IV. PREDICTIVE CONTROLLER DEVELOPMENT

### A. *Reduced order linear model identification*

The generalized MPC algorithm includes an identified linear state space model, used for predicting the plant output variables. The plant identified linear model were investigated around nominal operating conditions (i.e. supercritical conditions). Again GA has been used to identify the linear model with portions of data set.1 and 3 to match the response of the original process model. The prediction model has four states three inputs and three outputs. the linear model which has the following form:

$$\boldsymbol{x}(k+1) = \boldsymbol{Ax}(k) + \boldsymbol{Bu}(k) \qquad (1)$$

$$\boldsymbol{y}(k) = \boldsymbol{Cx}(k) \qquad (2)$$

The model has four states $\boldsymbol{x}^T=[x_1 \ \ x_2 \ \ x_3 \ \ x_4]^T$, three inputs or manipulated variables $\boldsymbol{u}^T=[u_1 \ \ u_2 \ \ u_3]^T$, and three outputs.$\boldsymbol{y}^T=[y_1 \ y_2 \ \ y_3]^T = [x_2 \ \ x_3 \ \ x_4]^T$. $\boldsymbol{A}$, $\boldsymbol{B}$, and $\boldsymbol{C}$, are the normalized state space model matrices. The parameters of the digitized model are:

$$\boldsymbol{A} = \begin{bmatrix} 0.7687 & 0.05486 & 0 & 0 \\ 0.7537 & 0.05379 & 0 & 0 \\ -0.003729 & -0.0002662 & 4.041\text{e-}018 & 0 \\ 18.94 & -23.78 & 0 & 1.0001 \end{bmatrix}$$

$$\boldsymbol{B} = \begin{bmatrix} 0.008409 & 0.01259 & -0.3041 \\ 0.008181 & 0.01243 & -0.3318 \\ 0.9934 & 1.249 & 21.75 \\ 0.2056 & 0.3123 & -8.338 \end{bmatrix}, \boldsymbol{C} = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

The inputs and the outputs which have been used for identification of the controlled plant are chosen as:

$$\begin{bmatrix} y_1 \\ y_2 \\ y_3 \end{bmatrix} = \begin{bmatrix} \text{Main steam pressure (MPa)} \\ \text{Electrical Power (MW)} \\ \text{Main steam temperature } (\text{C}^{\text{o}}) \end{bmatrix}$$

$$\begin{bmatrix} u_1 \\ u_2 \\ u_3 \end{bmatrix} = \begin{bmatrix} \text{Feedwater flow reference (Kg/s))} \\ \text{Raw coal flow reference (Kg/s)} \\ \text{Valve Position reference(p.u)} \end{bmatrix}$$

### B. *The generalized Predictive control strategy*

A model based predictive control is developed with provisions of unmeasured disturbances and measurement noises to be used for compensation around the investigated operating conditions. Here, the linear time invariant model is used for the MPC algorithm while the process mathematical model has been used to simulate the power plant responses. The controller setup is supposed to generate such states naturally by default. In this research, the generalized predictive controller algorithm described in [13] is adopted which has been widely used for chemical or thermodynamic process control [13] [14] [15] [16]. The prediction model has been upgraded as follows:

$$\boldsymbol{x}(k+1) = \boldsymbol{Ax}(k) + \boldsymbol{B}_u\boldsymbol{u}(k) + \boldsymbol{B}_v\boldsymbol{v}(k) + \boldsymbol{B}_W\boldsymbol{w}(k) \qquad (3)$$

$$\begin{aligned} \boldsymbol{y}(k) &= \boldsymbol{y}(k) + \boldsymbol{z}(k) \\ &= \boldsymbol{Cx}(k) + \boldsymbol{D}_u\boldsymbol{u}(k) + \boldsymbol{D}_v\boldsymbol{v}(k) + \boldsymbol{D}_W\boldsymbol{w}(k) + \boldsymbol{z}(k) \end{aligned} \qquad (4)$$

Where $\boldsymbol{v}$ is the measured disturbance and $\boldsymbol{w}$ is the unmeasured disturbance vector, $\boldsymbol{z}$ is the measurement noise. The adopted predictive control algorithm is quite analogous to LQG procedure, but with implication of the operational constraints. The prediction is made over a specific prediction horizon. Then the optimization program is executed on-line to calculate the optimal values of the manipulated variables to minimize the objective function below:

$$\xi(k) = \sum_{i=H_W}^{H_p} \left\| \boldsymbol{y}(k+i|k) - \boldsymbol{r}(k+i|k) \right\| \mathbf{Q} + \sum_{i=0}^{H_c-1} \left\| \boldsymbol{\Delta u}(k+i|k) \right\|^2 \mathbf{R} \ (5)$$

The weighting coefficients (**Q** and **R**), control interval ($H_w$), prediction horizon ($H_p$) and control horizon ($H_C$) of the performance objective function will affect the performance of the controller and computation time demands. The terms $\boldsymbol{r}$ represents the demand outputs used as a reference for MPC model and $\boldsymbol{\Delta u}$ is the change in control values for $H_C$ number of steps. Zero-order hold method is then used to convert the control signals from discrete time to continuous time to be fed to the plant. The inputs/outputs constraints are determined according to the power plant operation restrictions, which are expressed as the maximum and the minimum allowable inputs:

$$\boldsymbol{u}_{min} \leqslant \boldsymbol{u} \leqslant \boldsymbol{u}_{max} \qquad (6)$$

$$\Delta\boldsymbol{u}_{min} \leqslant \Delta\boldsymbol{u} \leqslant \Delta\boldsymbol{u}_{max} \qquad (7)$$

The optimization problem is to find the control moves for each manipulated variable, i.e. the MPC control law:

$$\min_{\Delta\boldsymbol{u},\dots,\Delta\boldsymbol{u}(k+1+H_C)} \xi(k) \qquad \text{subject to (6) and (7)}$$

The quadratic programming (QP) solver, with active set method or interior point method, is commonly used to solve control law problem of the MPC. In the interest of predictive controllers for thermal power stations, the generalized MPC approaches and DMC algorithms are reported for control of power plants once-through and drum type units. [3][4][5][7][14][15][16][17]. To show the influences of coal mill control on the plant output responses, a controller is implemented to regulate the primary air fan and the other is implemented to regulate the coal feeder speed. Both receive the MPC coal flow signal as adjuster for their reference. With the MPC strategy described above, simulations have been conducted. The whole package of the proposed strategy is shown in fig.8. Simulation results are presented in the next section.

## V. SIMULATION STUDIES

MPC tuning is finalized by selection appropriate values for the prediction horizon $H_p$, control horizon $H_C$, and weighting matrices **Q** and **R.** The control interval, prediction, and control horizons are found to be 1, 35, 5seconds respectively. **Q**= [1 1 1] and **R**=[0.1 0.1 0.1]. Simulating different scenarios have lead to this selection. In this scenario, a step change of ±20MW in the power is assumed as set-point signal, the pressure set-point is rescheduled from look-up table which relates the power set-point to the pressure, and the temperature set-point is constant of 570C°. In the reported results for Case A represent the improved case with using MPC as correction to the mill local control, boiler feedwater flow, and turbine valve controller and Case B represent existing milling and plant performance. From the reported results, the improvements are obvious in case of using the MPC without violating the practical constrains of the various plant variables. Thus the primary air fan and feeder speed can be regarded as other supplementary means to improve the power primary response, not only acting the turbine expansion valves.

Furthermore, the boiler steam pressure and temperature have less fluctuation around the set-point which helps in extending the life of the equipment. The pulverized coal flow to the furnace, the feedwater flow, and valve position are mentioned in fig.10, more pulverized coal is discharged to the furnace from the mills per time unit which means more coal is combusted and more energy is delivered from the boiler to give quicker responses. Hence, the MPC and its associated strategy for reference correction control play an important role in improving the plant responses and satisfying the regulations of the national grid code. Especially when increasing the grinding capability of the mills and pulverized coal discharging speed. Fig.11 shows major mill variables. High mill differential pressure and primary air pressure are created to carry more coal flow to the burners. Also higher raw coal is initially dropped in the mill because of the improved feeder speed response. The mass of raw coal and pulverized coal in the mill is higher to provide the required flow of pulverized coal in a timely manner. The only penalty which has been paid is that more current, and consequently, power is consumed from the mills to increase the grinding capability of the mills.

## VI. CONCLUSION AND FUTURE RESEARCH

In this paper, a complete power plant process model including fuel preparation milling process. The model prepared a platform for us to investigate the influences of mill control to the whole power plant responses. A new strategy of applying model predictive control is reported and the new contribution for the strategy is to use the MPC to update the control set-up/desired values instead of tuning the individual local loop controllers. This improved the power plant responses over the existing control strategy. As a future recommendation, it is suggested to extend the method of modeling and control to ultra-supercritical power plant.

*Abstract*—**This paper discusses the design and route to implementation of a regenerative braking system for a Renewable Hydrogen Hybrid Electric Vehicle (RHHEV) that would performs regenerative energy recovery based on vehicle attributes, thereby providing improved performance. A dynamic model of a regenerative braking system for a RHHEV has been derived and implemented in MATLAB/Simulink. The model is then incorporated into a simulation model of a RHHEV to analyze the energy management effects of integrating the regenerative braking into the system. Simulations are carried out and the results are discussed in this paper. The results indicate that this approach provides an improvement in performance and fuel efficiency to the RHHEV system.**

***Keywords – Hydrogen vehicles, Renewable energy, Regenerative braking, Energy sources, Energy recovery***

## I. INTRODUCTION

The utilization of regenerative braking (RB) makes the hydrogen fuel cell vehicles more attractive by better utilising the on board storage capacity for hydrogen, through raised energy efficiency. RB systems could recover the energy that would otherwise be lost through braking [1]. The results from previous research efforts show that, significant amount of energy can be recovered by the integration of a regenerative braking mechanism [2]. Further research effort should focus on the development of a systematic and integrated regenerative braking system to recover as much energy as possible, while maintaining suitable power flows in the other subsystems. To this end, several researchers have developed many different configurations of energy recovery mechanisms to continuously recover otherwise dissipated energy that occurs due to road irregularities, vehicle acceleration, and braking; see for example [3]-[9].

In this paper, developments in energy recovery mechanisms for renewable hydrogen hybrid electric vehicle (RHHEV) systems are described. Essentially and in general terms there are two approaches to such energy recovery mechanisms; implementation of a better energy management system by providing optimal powertrain topologies applied to the various energy sources and incorporating an energy recovery mechanism [10]. This work addresses both approaches by describing an optimal power management strategy for RHHEV systems for better energy management and the development of a regenerative braking system (RBS) for energy recovery. This paper begins with a discussion of RB techniques and this is followed by the incorporation of the RB system into an optimal power management strategy for RHHEV and analyses.

## II. REGENERATIVE BRAKING SYSTEM

The energy efficiency and driving range of the RHHEV system may be increased through the development and incorporation of RBS. The regenerative braking methods have the capability to increase hybrid electric vehicle (HEV) driving range by approximately10-30% [11]. Further benefits of RBS are that they can reduce the drawdown of battery charge, extend the overall life of the battery pack and reduce fuel consumption. However, the main problem with RBS is that at low speed, the electric motor may not be able to produce enough torque to stop the vehicle [12], [13]. The goal of the RBS is to recover some of the energy otherwise wasted as braking heat and store it, and then later use it for vehicular motion. The principle of a RBS circuit is shown in Fig.1. This is commonly known to represent the conditions for four quadrants of possible operation for the regenerative braking [14], [15].

In forward motoring (quadrant I) $v_a$ , $E_g$ , and $I_a$ are all positive. The torque and speed are also positive in this quadrant. During forward braking (quadrant II), the motor runs in the forward direction and the induced emf $E_g$ will continue to be positive. For the torque to be negative and the direction of the energy flow to reverse, the armature current must be negative. The supply voltage $v_a$ should be keep less than $E_g$ . In reverse motoring (quadrant III), $v_a$ , $E_g$ , and $I_a$

are all negative. The torque and speed are also negative in this quadrant. To keep the torque negative and the energy flow from the source to the motor, the back emf $E_g$ must satisfy the condition $|v_a| > |E_g|$.

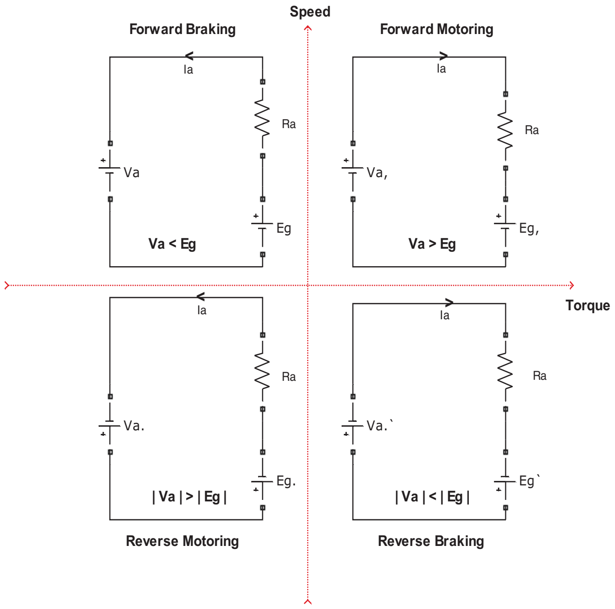

Fig.1 Principle of RBS

The polarity of $E_g$ can be reversed by changing the direction of field current or by reversing the armature terminals. During reverse braking (quadrant IV), the motor runs in the reverse direction. $v_a$ and $E_g$ will continue to be negative. For the torque to be positive and the energy to flow from the motor to the source, the armature current must be positive. The induced emf $E_g$ must satisfy the condition $|v_a| < |E_g|$.

Using this fundamental principle, there are many different types of energy recovery system that have been developed. These range from electro-hydraulic braking (EHB) systems to energy harvesting shock absorber [16]-[20]. In this paper, a simulation model of a simple regenerative braking system is developed and implemented in MATLAB/Simulink™ and incorporated into a vehicle simulator previously developed [21] to analyse the effect of integrating the RBS. The vehicle model used here is for the University of Glamorgan hydrogen bus (UoGHB). The powertrain of UoGHB consist of 12kW PEM fuel cell stack developed by Hydrogenics, a 288v, 132 Amp-hr battery pack, 375v, 63F Maxwell ultracapacitor and 70kW DC motor. Simulations are carried out on the New European Drive Cycle (NEDC) shown in Fig.2.

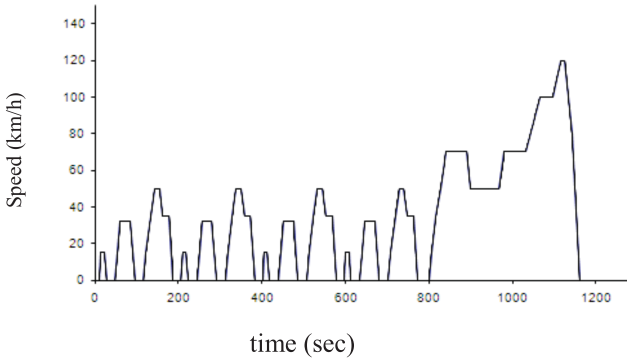

Fig.2 New European Drive Cycle

The combined power sources (fuel cell, battery and ultracapacitor) in a RHHEV provide a more viable solution than a single power source renewable vehicle [10]. The fuel cell system provides low to medium constant power delivery, whereas the lead acid battery pack provides medium constant power. Finally the ultracapacitors (UC) deliver a large, instantaneous power demand, which is ideal for high load acceleration and regeneration from braking power [22].

The regenerative braking is only possible, if there is enough torque applied to the wheels, in accordance with the driving conditions. These requirements may be expressed in and governed by the following equations [2], [5], [6]:

The regenerative torque applied to the front wheels $\tau_R$ is given by;

$$\tau_R = \eta\phi\tau_{RB} \qquad (1)$$

Where, $\eta$ is the efficiency, $\phi$ is the continuously variable transmission speed ratio and by considering that the motor has a reversible performance characteristic curve; $\tau_{RB}$ is the regenerative torque provided by the motor which is determined from the motor characteristic curve for the given speed [2] and is described as follows;

$$\tau_{RB} = \varpi_f(b_{soc}, v)\tau_m \qquad (2)$$

Where, $\varpi_f$ is the weighting factor and it depends on the battery state of charge $b_{soc}$ and vehicle velocity $v$. $\tau_m$ is the electric motor torque. The regenerative braking force at the wheels $F_{RB}$ is obtained as;

$$F_{RB} = \tau_R . r_t^{-1} \qquad (3)$$

Where, $\tau_R$ is the regenerative torque applied to the front wheel, $r_t$ is the tyre radius and $F_{bf}$ is the required front wheel braking force. If $F_{RB} > F_{bf}$ then the front wheel is braked only by the regenerative brake. Otherwise the regenerative braking needs to be combined with conventional friction braking. Suppose, the hydraulic friction brake works with the regenerative brake, then in this case the change in hydraulic pressure in the front wheel cylinder $\Delta P$ is given by;

$$\Delta P = \tau_{RB}(\lambda A \times 2r_e)^{-1} \quad (4)$$

Where, $\lambda$ is the friction coefficient, $A$ is the front wheel cylinder area and $r_e$ is the effective radius. So, the supplied hydraulic pressure $P_h$ is calculated as;

$$P_h = P_s - \Delta P \quad (5)$$

Where, $P_s$ is the master cylinder pressure. Finally, the total braking torque $\tau_{BK}$ at the front wheel is given by;

$$\tau_{BK} = \tau_R + \tau_{fr} \quad (6)$$

Where, $\tau_{fr}$ is the torque provided by conventional friction braking.

From the above analyses it is clear that the amount of regenerative brake energy depends on available motor torque, which will vary according to battery state of charge (SOC), motor speed and corresponding driver demands. It is desirable that the system use the least possible stored energy to provide the required motive or ancillary demands. This can be achieved by using energy saving mechanisms or power management algorithms [23]. Therefore, in this paper an optimal power management strategy is also integrated into the configuration of a RHHEV system with RBS. The system analyses and performances are described in the following sections.

## III. Power management of RHHEV with RBS

RHHEV has become increasingly of interest in the powertrain industry due to the finite supply of fossil fuels and the effects fossil fuels are having on the environment [10]. Hybrid electric vehicle (HEV) developments play an important role in the realisation of the renewable hydrogen hybrid electric vehicles. $CO_2$ emission reduction and possible fuel economy benefits are attractive functions of HEV systems. RHHEV's are expected to make a significant contribution to the environmental needs/demands of the premium vehicle sector. However, combining a polymer electrolyte membrane fuel cell (PEM FC) stack, UC module, with a battery pack; while managing power flow and meeting the high expectations of the market, presents challenges in the area of system configuration and controller design [10]. The system configuration and controller design for HEV systems can be complex and challenging. The control system design requires a high level of integration with existing systems on the vehicle.

The literature contains several publications concerning various aspects of HEV system power distribution methodologies and controller design; see for example, [9], [18], [19]. Broader details of the subject can be found in various reports, which summarise the power management aspects and problems experienced with HEV [22]-[24]. These reports also suggest some technical solutions and analytical methods for application to some of the problems. These range from control algorithms for global optimization, based on *a priori* knowledge of a scheduled driving cycle, to real-time power management based on optimal control theory [23].

Previous power management design efforts focussed on the design methods to determine the component sizes that minimized the cost of the power system elements in HEV [25]. Furthermore, power management strategies and component sizing are often coupled together, which implies that different component sizing might be associated with different power management strategies. Therefore both should be considered as a combined package. Many other research efforts on power distribution in HHEV have been expanded. These include; the use of an equivalent consumption minimization strategy to determine the real time optimal power distribution of a fuel cell/UC hybrid vehicle [26]. In this study, an optimal power management strategy for HHEV systems described in [23] is adopted and integrated with the RBS, in order to maximize the benefit of the RBS. The power source configuration of the RHHEV is shown in Fig.3.

The DC-link is the connection mechanism between the electrochemical power source and the motor. The DC-link is kept at a constantly high voltage, thereby assuring the highest possible motor torque over the whole speed range. Since the voltage of the power sources may vary, a DC/DC converter is needed in the configuration (see Fig.3).

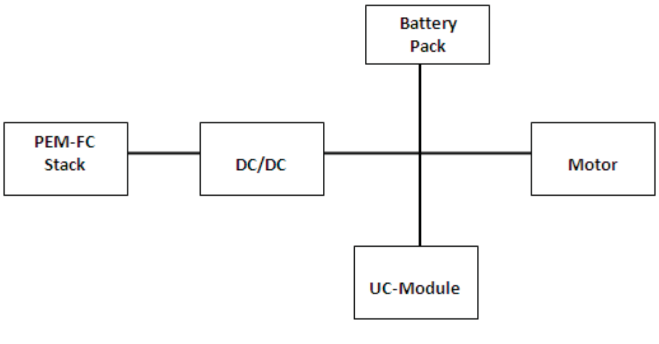

Fig.3 Power source configuration of a HHEV system

The power balance equation for the overall RHHEV system is given by;

$$p_{fc} + p_{uc} + p_b = p_d \qquad (7)$$

where $p_{fc}$, is the output power of the PEM fuel cell stack, $p_{uc}$, the output power of the ultracapacitor, $p_b$ the output power of the battery pack and $p_d$, the power demand. The regenerated power of the battery is calculated as;

$$p_{RB} = p_b - i^2 R \qquad (8)$$

The combined system with RBS and optimal power management (PM) is implemented in MATLAB/Simulink™ and simulated using the UoGHB vehicle simulator [21].

## IV. Results and Discussion

The simulation results show that by using this regenerative braking (RBS) mechanism with an optimal power management strategy, a considerable amount of energy can be recovered. The results indicate that the combined optimal power management strategy with RBS has significantly improved the RHHEV system efficiency and total power recovery.

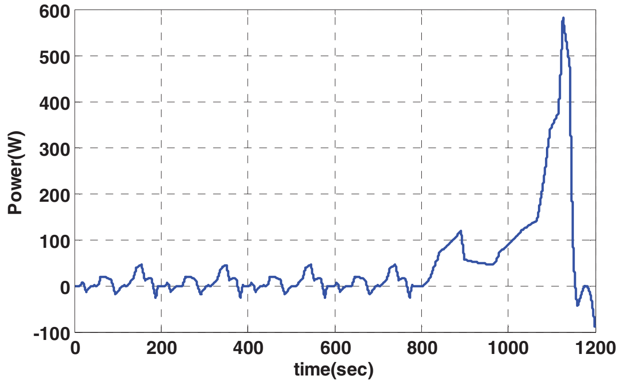

Fig.4 power requirements

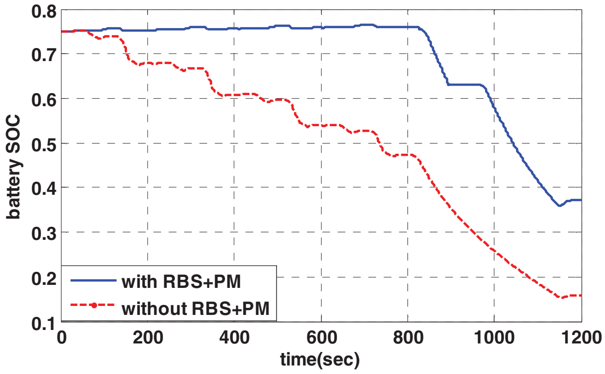

Fig.5 Compared responses of battery SOC

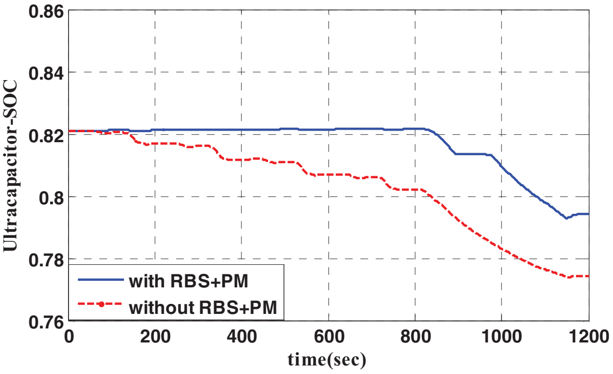

Fig.6. Compared responses of Ultracapacitor- SOC

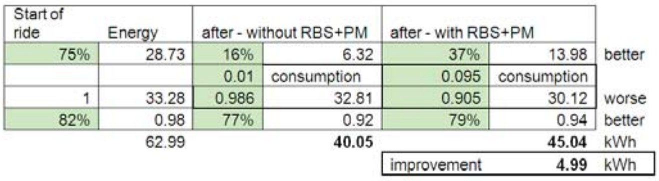
In Fig.4 the total power requirements for the whole NEDC is shown. The combined power sources (battery, ultracapacitor and fuel cell) will provide the power to RHHEV for the required driver demand. Fig.5 & 6 shows a comparison of the charge/discharge characteristics of battery pack SOC and ultracapacitors respectively. It may be realised from these results that, due to the regenerative energy recovery and the inclusion of the optimal power management strategy the state of charge of these power sources are kept high (apart from at higher power demand) and able to provide constant power. The energy required in any given HEV system depends on the systems design and operation characteristics and the quantity and type of losses encountered during vehicular motion. In this paper the energy requirement for the HHEV system is analysed with reference to the UoGHB. The system model includes the regenerative energy recovery mechanism, thus it is of interest from an energy system point of view. It is therefore, essential to search for design and operating conditions which lead to reduction of energy dissipation and consequently lower production cost to promote the HHEV system. To this end, the UoGHB model is used to show the improvement of energy consumption via system analysis, which includes the regenerative energy recovery and power management.

Summary of energy consumption for both cases (with and without RBS plus PM) are shown in Table 4.1. In energy terms the maximum energy capacity of the battery pack and UC modules installed in the UoGHB is 38.3 kWh and 1.2 kWh respectively and energy capacity of the hydrogen fuel tank is 33.28 kWh. Usually battery/UC states of charge are kept to particular limits (or constant) to increase the life of the battery. This leads to variable usage of hydrogen and it can be controlled by incorporating an optimal control algorithm and energy saving mechanisms. In this paper for the simulation analysis, the NEDC is used and at the start of the journey it is assumed that the hydrogen tank is full and the battery SOC and UC-SOC are at 75 and 82 % respectively (see Fig.5 & 6). In energy term this is about 28.73 kWh and 0.98 kWh respectively. If the RBS and PM are not included, at the end of the journey, energy left in the battery is about 6.32 kWh (16%) and in UC is about 0.92 kWh (77%). With the inclusion of the RBS and PM the energy remaining in battery and UC is about

13.98 kWh (37%) and 0.94 kWh (79%) respectively. However, the hydrogen fuel usage was high in comparison with the system without RBS and PM. This is due to the arrangements of power management and system configuration. In this case the FC-stack is considered to be the main power source to supply the power. But, it should be noted that overall a significant improvement is achieved in energy saving by incorporating RBS and PM. The improvement is about 4.9 kWh energy saving. Thus, the system efficiency is improved by about 27%.

Table 4.1 summary of energy consumption



| Start of ride | Energy | after - without RBS+PM | | after - with RBS+PM | | |
|---|---|---|---|---|---|---|
| 75% | 28.73 | 16% | 6.32 | 37% | 13.98 | better |
| | | 0.01 | consumption | 0.095 | consumption | |
| 1 | 33.28 | 0.986 | 32.81 | 0.905 | 30.12 | worse |
| 82% | 0.98 | 77% | 0.92 | 79% | 0.94 | better |
| | 62.99 | | **40.05** | | **45.04** | kWh |
| | | | | improvement | **4.99** | kWh |

The energy consumption in any HEV system is one of the important parameters that dictate the choice of the HEV. In addition to the energy consumption the cost of the technology and the final cost of the vehicle determine the choice of the HEV system.

## V. Concluding Remarks

In this paper, an investigation of the development of a RBS with an optimal PM strategy for a RHHEV system was carried out. A dynamic model of a RBS with an optimal PM strategy has been described and implemented in MATLAB/Simulink. The model was then incorporated into a UoGHB simulator to analyse the effect of the integration of the regenerative braking mechanism. The results show that if such mechanisms are used in the UoGHB, about 4.9kWh energy could be saved during the whole NEDC. Thus, it can be concluded that in general using such a mechanism in any HHEV system is likely to a significant amount of energy being recovered.

*Abstract*—**This paper is concerned with the finite-horizon recursive filtering problem for a class of nonlinear time-varying systems with missing measurements. The missing measurements are modeled by a series of mutually independent random variables obeying Bernoulli distributions with possibly different occurrence probabilities. Attention is focused on the design of a recursive filter such that, for the missing measurements, an upper bound for the filtering error covariance is guaranteed and such an upper bound is subsequently minimized by properly designing the filter parameters at each sampling instant. The desired filter parameters are obtained by solving two Riccati-like difference equations that are of a recursive form suitable for online applications. A simulation example is exploited to demonstrate the effectiveness of the proposed filter design scheme.**

## I. Introduction

The past few decades have seen a surge of research interest on the filtering or state estimation theories due to their extensive applications in a variety of practical areas including weather forecasting, economics, radar tracker and global positioning system. Up to now, a great deal of efforts has been delivered to the design issues of various kinds of filters, for example, Kalman filters [2], [16], [22], extended Kalman filters [9], [11], [24], [25] and $H_\infty$ filters [1], [6], [10], [12], [15], [23], [28]. Among them, the traditional Kalman filter has been shown to be an optimal one in the sense of minimum variance for the linear systems, and the extended Kalman filter has been developed to serve as an effective way for handling the nonlinear estimation problems. Recently, the robust extended Kalman filtering problem has been tackled in [24] for a class of nonlinear systems, and a filtering algorithm has been presented in a recursive form suitable for online applications.

Most traditional filter design approaches rely on the assumption that the measurement signals are perfectly transmitted. Such an assumption, however, is conservative in many engineering practice presented with unreliable communication channels. For example, due to temporal sensor failures or network congestions, the system measurements may contain noise only at certain time points and the true signals are simply missing. As such, the control and filtering problems with missing measurements have received considerable research attention, see e.g. [5], [8], [13], [14], [18]–[21], [27]. A common way for modeling the data missing is to introduce a random variable satisfying the Bernoulli binary distribution taking values on either 1 or 0, where 1 is for the perfect signal delivery and 0 represents the measurement missing. Most of the aforementioned results have been based on the hypothesis that all sensors have identical failure characteristics [8]. However, such a hypothesis may not be true in the case that the signals are observed by multiple sensors and each individual sensor may have different failure rate.

It is worth mentioning that most existing results regarding the missing measurements have concentrated on *linear* systems. It is well known that the nonlinearity is a ubiquitous feature in almost all practical systems, and the occurrence of the nonlinearity inevitably degrades the system performance and even leads to instability [25], [26]. However, so far, the filtering problem for *general nonlinear* stochastic systems with missing measurements has not been thoroughly investigated yet, not to mention the case where multiple sensors undergo probabilistic missing measurements. It is, therefore, our aim of this paper to shorten the gap by initiating a study on such a challenging issue.

Motivated by the above discussions, we aim to investigate the recursive filtering problem for a class of nonlinear time-varying systems with missing measurements. A series of mutually independent random variables are introduced to describe the phenomenon of missing measurements where individual sensor is allowed to have different missing probability. The finite-horizon filter is designed such that an upper bound on the filtering error covariance is guaranteed and such an upper bound is subsequently minimized by the designed filter at each sampling instant. The proposed filter scheme is given in terms of the solutions to two Riccati-like difference equations, and therefore the algorithm is suitable for recursive computations.

**Notations.** The notations used throughout the paper are standard. $R^n$ and $R^{n\times m}$ denote the $n$-dimensional Euclidean space and the set of all $n \times m$ matrices, respectively. For a matrix $P$, $P^T$ and $P^{-1}$ represent its transpose and inverse, respectively. $\mathrm{tr}(\cdot)$ stands for the trace of a matrix. $\circ$ is the Hadamard product defined as $[A \circ B]_{ij} = A_{ij} \cdot B_{ij}$. $E\{x\}$ stands for the expectation of the stochastic variable $x$. $I$ and $0$ represent the identity matrix and the zero matrix with appropriate dimensions, respectively. $\mathrm{diag}\{X_1, X_2, \ldots, X_n\}$ stands for a block-diagonal matrix with matrices $X_1, X_2, \ldots, X_n$ on the diagonal. Matrices, if their dimensions are not explicitly stated, are assumed to be compatible for algebraic operations.

## II. Problem Formulation and Preliminaries

Consider the following class of time-varying nonlinear systems:

$$\begin{aligned} x_{k+1} &= f(x_k) + D_k\omega_k && (1) \\ y_k &= \Xi_k C_k x_k + \nu_k && (2) \end{aligned}$$

where $x_k \in R^n$ is the system state to be estimated, the initial value $x_0$ has mean $\bar{x}_0$ and covariance $P_{0|0}$, $y_k \in R^m$ is the output vector, $\omega_k \in R^r$ is the process noise with zero-mean and covariance $Q > 0$, and $\nu_k \in R^m$ is the zero-mean measurement noise with covariance $V > 0$. The nonlinear function $f(x_k)$ is analytic everywhere with known form, $C_k$ and $D_k$ are known and bounded matrices with appropriate dimensions. $\Xi_k = \mathrm{diag}\{\xi_k^1, \xi_k^2, \ldots, \xi_k^m\}$ is to account for the missing measurements where the mutually uncorrelated (in $k$ and $i$) random variables $\xi_k^i \in R$ $(i = 1, 2, \ldots, m)$ take values of 1 and 0 with

$$\begin{aligned} \mathrm{Prob}\left\{\xi_k^i = 1\right\} &= E\left\{\xi_k^i\right\} := \vartheta_k^i, && (3) \\ \mathrm{Prob}\left\{\xi_k^i = 0\right\} &= 1 - E\left\{\xi_k^i\right\} := 1 - \vartheta_k^i. && (4) \end{aligned}$$

Here, $\vartheta_k^i \in [0, 1]$ is a known constant, $\xi_k^i$ is assumed to be independent with $\omega_k$, $\nu_k$ and $x_0$. Also, the noise signals mentioned above are uncorrelated with each other.

In this paper, we design a filter of the following form:

$$\begin{aligned} &\hat{x}_{k+1|k} = f\left(\hat{x}_{k|k}\right), && (5) \\ &\hat{x}_{k+1|k+1} = \hat{x}_{k+1|k} + K_{k+1}\left(y_{k+1} - \bar{\Xi}_{k+1}C_{k+1}\hat{x}_{k+1|k}\right) && (6) \end{aligned}$$

where $\hat{x}_{k|k}$ is the estimate of $x_k$ at time $k$ with $\hat{x}_{0|0} = \bar{x}_0$, $\hat{x}_{k+1|k}$ is the one-step prediction at time $k$, $K_{k+1}$ is the filter parameter to be determined, and $\bar{\Xi}_{k+1} := E\{\Xi_{k+1}\} := \mathrm{diag}\{\vartheta_{k+1}^1, \vartheta_{k+1}^2, \ldots, \vartheta_{k+1}^m\}$.

The objective of this paper is twofold. First, we aim to design a finite-horizon filter of form (5)-(6) such that, for the missing measurements, an upper bound for the filtering error covariance is guaranteed, i.e., there exists a sequence of positive-definite matrices $\Sigma_{k+1|k+1}$ $(0 \le k \le N)$ satisfying

$$\begin{aligned} &E\left\{\left(x_{k+1} - \hat{x}_{k+1|k+1}\right)\left(x_{k+1} - \hat{x}_{k+1|k+1}\right)^T\right\} \\ &\le \Sigma_{k+1|k+1} \end{aligned} \qquad (7)$$

Second, we shall minimize such an upper bound $\Sigma_{k+1|k+1}$ by appropriately designing the filter parameter at each sampling instant.

**Remark 1** In the model (2), $C_k x_k$ represents the measurement output subject to probabilistic information loss characterized by the matrix $\Xi_k$, and $\nu_k$ is the random exogenous noise acting on the measurement output. In other words, the model (2) is comprehensive to include the practical cases of probabilistic missing measurements and external additive disturbances, thereby reflecting the engineering practice in a more realistic way.

**Remark 2** In this paper, the phenomena of measurements missing is considered. Owing to the sensors aging and/or sensor temporal failure, the missing measurements may occur intermittently. In (2), $\Xi_k$ is introduced to characterize the missing measurements where the random variable $\xi_k^i$ $(i = 1, 2, \ldots, m)$ corresponds to the $i$ sensor operating at the $k$th sampling time point. For different sensors, it would be more reasonable to allow multiple sensors to have different missing probabilities (or failure rates [8]).

Before ending this section, we recall the following lemmas which will be frequently used in subsequent developments.

**Lemma 1** [7] Let $A = [a_{ij}]_{n\times n}$ be a real-valued matrix and $B = \mathrm{diag}\{b_1, b_2, \ldots, b_n\}$ be a diagonal stochastic matrix. Then

$$E\{BAB^T\} = \begin{bmatrix} E\{b_1^2\} & E\{b_1b_2\} & \cdots & E\{b_1b_n\} \\ E\{b_2b_1\} & E\{b_2^2\} & \cdots & E\{b_2b_n\} \\ \vdots & \vdots & \ddots & \vdots \\ E\{b_nb_1\} & E\{b_nb_2\} & \cdots & E\{b_n^2\} \end{bmatrix} \circ A$$

where $\circ$ is the Hadamard product.

**Lemma 2** [22] Given matrices $A$, $H$, $G$ and $F$ with appropriate dimensions such that $FF^T \le I$. Let $X$ be a symmetric positive definite matrix and $\gamma$ be an arbitrary positive constant such that $\gamma^{-1}I - GXG^T > 0$. Then the following inequality holds

$$\begin{aligned} &(A + HFG)X(A + HFG)^T \\ \le\ &A\left(X^{-1} - \gamma G^TG\right)^{-1}A^T + \gamma^{-1}HH^T. \end{aligned} \qquad (8)$$

**Lemma 3** [17] For $0 \le k \le N$, suppose that $X = X^T > 0$, $S_k(X) = S_k^T(X) \in R^{n\times n}$ and $H_k(X) = H_k^T(X) \in R^{n\times n}$. If

$$S_k(Y) \ge S_k(X), \ \ \forall\ X \le Y = Y^T \qquad (9)$$

and

$$H_k(Y) \ge S_k(Y), \qquad (10)$$

then the solutions $M_k$ and $N_k$ to the following difference equations

$$M_{k+1} = S_k(M_k), \ \ N_{k+1} = H_k(N_k), \ \ M_0 = N_0 > 0 \qquad (11)$$

satisfy $M_k \le N_k$.

## III. Main results

In this section, a sufficient condition for the design of filter parameters is established by solving two Riccati-like difference equations.

To proceed, denote the one-step prediction error as $\tilde{x}_{k+1|k} = x_{k+1} - \hat{x}_{k+1|k}$ and the filtering error as $\tilde{x}_{k+1|k+1} = x_{k+1} - \hat{x}_{k+1|k+1}$. Subtracting (5) from (1), we obtain

$$\tilde{x}_{k+1|k} = f\left(x_k\right) - f\left(\hat{x}_{k|k}\right) + D_k\omega_k. \tag{12}$$

By using the Taylor series expansion around $\hat{x}_{k|k}$, we linearize $f\left(x_k\right)$ as follows:

$$f\left(x_k\right) = f\left(\hat{x}_{k|k}\right) + A_k\tilde{x}_{k|k} + o(|\tilde{x}_{k|k}|) \tag{13}$$

where

$$A_k = \frac{\partial f\left(x_k\right)}{\partial x_k}|_{x_k=\hat{x}_{k|k}},$$

and $o(|\tilde{x}_{k|k}|)$ stands for the high-order terms of the Taylor series expansion. For presentation convenience, along the similar line of [3], [25], the high-order terms are transformed into the following easy-to-handle formulation:

$$o(|\tilde{x}_{k|k}|) = B_k\Omega_k L_k\tilde{x}_{k|k}, \tag{14}$$

where $B_k$ is a bounded problem-dependent scaling matrix, $L_k$ is a bounded matrix for providing an extra degree of freedom to tune the filter, and $\Omega_k$ is an unknown time-varying matrix accounting for the linearization errors of the dynamical model and satisfies

$$\Omega_k\Omega_k^T \leq I. \tag{15}$$

**Remark 3** In traditional extended Kalman filter algorithms, the Taylor series expansion is employed to linearize the nonlinearity $f(x_k)$, and the linearization errors are simply neglected which would inevitably lead to conservatism in certain cases. Recently, a new approach has been proposed in [3] to describe the higher-order terms in the Taylor series in terms of parameter uncertainties. In this paper, as in [3], [24], we use the deterministic matrix $\Omega_k$ and the scaling matrix $B_k$ in (14)-(15) to account for the linearization errors in obtaining the matrix $A_k$. For more details we refer the reader to Appendix C of [3] where a nice interpretation has been given. It is worthwhile to further mention that, in practice, the high-order terms in the Taylor series expansion are commonly bounded and it is reasonable to regard them as deterministic uncertainties affecting the system matrix $A_k$.

It follows from (12)-(14) that the one-step prediction error is given by

$$\tilde{x}_{k+1|k} = \left(A_k + B_k\Omega_k L_k\right)\tilde{x}_{k|k} + D_k\omega_k. \tag{16}$$

On the other hand, it follows from (6) that the filtering error $\tilde{x}_{k+1|k+1}$ can be described by

$$\begin{aligned}&\tilde{x}_{k+1|k+1}\\ &= \left(I - K_{k+1}\bar{\Xi}_{k+1}C_{k+1}\right)\tilde{x}_{k+1|k} - K_{k+1}\nu_{k+1}\\ &\quad - K_{k+1}\left(\Xi_{k+1} - \bar{\Xi}_{k+1}\right)C_{k+1}x_{k+1}\end{aligned} \tag{17}$$

Based on (16) and (17), we are ready to present the following lemmas which give the recursion of the one-step prediction error covariance and filtering error covariance, respectively.

**Lemma 4** The one-step prediction error covariance $P_{k+1|k}$ obeys the following recursion:

$$\begin{aligned}P_{k+1|k} =& \left(A_k + B_k\Omega_k L_k\right)P_{k|k}\left(A_k + B_k\Omega_k L_k\right)^T\\ &+ D_kQD_k^T\end{aligned} \tag{18}$$

where $P_{k|k} = E\{\tilde{x}_{k|k}\tilde{x}_{k|k}^T\}$ is the filtering error covariance.

**Proof** Since (18) follows from (16) directly, the proof is omitted for brevity.

**Lemma 5** The filtering error covariance $P_{k+1|k+1}$ is given as follows:

$$\begin{aligned}&P_{k+1|k+1}\\ &= \left(I - K_{k+1}\bar{\Xi}_{k+1}C_{k+1}\right)P_{k+1|k}\left(I - K_{k+1}\bar{\Xi}_{k+1}C_{k+1}\right)^T\\ &\quad + K_{k+1}(J_{k+1} + V)K_{k+1}^T\end{aligned} \tag{19}$$

where

$$\begin{aligned}J_{k+1} :=& \breve{\Xi}_{k+1} \circ \left(C_{k+1}E\left\{x_{k+1}x_{k+1}^T\right\}C_{k+1}^T\right),\\ \breve{\Xi}_{k+1} :=& \mathrm{diag}\{\vartheta_{k+1}^1\left(1 - \vartheta_{k+1}^1\right), \vartheta_{k+1}^2\left(1 - \vartheta_{k+1}^2\right),\\ &\ldots, \vartheta_{k+1}^m\left(1 - \vartheta_{k+1}^m\right)\}.\end{aligned} \tag{20}$$

**Proof** According to (17), we have

$$\begin{aligned}&P_{k+1|k+1}\\ &= \left(I - K_{k+1}\bar{\Xi}_{k+1}C_{k+1}\right)P_{k+1|k}\left(I - K_{k+1}\bar{\Xi}_{k+1}C_{k+1}\right)^T\\ &\quad + K_{k+1}E\{\left(\Xi_{k+1} - \bar{\Xi}_{k+1}\right)C_{k+1}x_{k+1}x_{k+1}^TC_{k+1}^T\\ &\quad \times \left(\Xi_{k+1} - \bar{\Xi}_{k+1}\right)\}K_{k+1}^T + K_{k+1}VK_{k+1}^T.\end{aligned} \tag{21}$$

Next, applying Lemma 1 and together with the property of conditional expectation, we obtain

$$\begin{aligned}&E\{\left(\Xi_{k+1} - \bar{\Xi}_{k+1}\right)C_{k+1}x_{k+1}x_{k+1}^T\\ &\times C_{k+1}^T\left(\Xi_{k+1} - \bar{\Xi}_{k+1}\right)\}\\ =&\breve{\Xi}_{k+1} \circ \left(C_{k+1}E\left\{x_{k+1}x_{k+1}^T\right\}C_{k+1}^T\right)\end{aligned} \tag{22}$$

where $\breve{\Xi}_{k+1}$ is defined in (20). Therefore, (19) follows directly from (21) and (22), and the proof of this Lemma is complete.

**Remark 4** It can be seen that the linearization has been enforced to facilitate the recursive filtering algorithm developments. From Lemmas 4-5, the filtering error covariance can be obtained for the missing measurements provided that the matrix equations (18) and (19) are solvable. Unfortunately, due to the consideration of the nonlinearity, (18) and (19) are contaminated by some uncertain terms $\Omega_k$ and $E\left\{x_{k+1}x_{k+1}^T\right\}$, which lead to essential difficulty in determining the accurate value of the filtering error covariance $P_{k+1|k+1}$. In the following, an alternatively way is employed to design an appropriate filter parameter $K_{k+1}$ such that there exists an upper bound for the filtering error covariance.

Now, we are in a position to present our main results. In view of Lemmas 2-5, the filter parameter is designed such that an optimized upper bound for the filtering error covariance is achieved at each sampling instant.

**Theorem 1** Consider the one-step prediction error covariance and the filtering error covariance in (18)-(19), respectively. Assume that (15) holds. Let $\gamma_k$ and $\varepsilon$ be positive scalars.

If the following two Riccati-like difference equations

$$\begin{aligned}&\Sigma_{k+1|k}\\ &=A_k\left(\Sigma_{k|k}^{-1}-\gamma_k L_k^T L_k\right)^{-1}A_k^T+\gamma_k^{-1}B_kB_k^T\\ &\quad+D_kQD_k^T,\end{aligned} \tag{23}$$

and

$$\begin{aligned}&\Sigma_{k+1|k+1}\\ &=\left(I-K_{k+1}\bar{\Xi}_{k+1}C_{k+1}\right)\Sigma_{k+1|k}\\ &\quad\times\left(I-K_{k+1}\bar{\Xi}_{k+1}C_{k+1}\right)^T+K_{k+1}\\ &\quad\times\left[\check{\Xi}_{k+1}\circ\left(C_{k+1}\Phi_{k+1|k}C_{k+1}^T\right)+V\right]K_{k+1}^T\end{aligned} \tag{24}$$

with initial condition $\Sigma_{0|0}=P_{0|0}>0$ have positive-definite solutions $\Sigma_{k+1|k}$ and $\Sigma_{k+1|k+1}$ such that, for all $0\le k\le N$, the following constraint

$$\gamma_k^{-1}I-L_k\Sigma_{k|k}L_k^T>0, \tag{25}$$

are satisfied where

$$\Phi_{k+1|k}:=(1+\varepsilon)\,\Sigma_{k+1|k}+\left(1+\varepsilon^{-1}\right)\hat{x}_{k+1|k}\hat{x}_{k+1|k}^T, \tag{26}$$

then with the filter parameter $K_{k+1}$ given by

$$\begin{aligned}&K_{k+1}\\ &=\Sigma_{k+1|k}C_{k+1}^T\bar{\Xi}_{k+1}\Big[\bar{\Xi}_{k+1}C_{k+1}\Sigma_{k+1|k}C_{k+1}^T\bar{\Xi}_{k+1}\\ &\quad+\check{\Xi}_{k+1}\circ\left(C_{k+1}\Phi_{k+1|k}C_{k+1}^T\right)+V\Big]^{-1}\end{aligned} \tag{27}$$

the matrix $\Sigma_{k+1|k+1}$ is an upper bound for $P_{k+1|k+1}$, i.e.,

$$P_{k+1|k+1}\le\Sigma_{k+1|k+1}. \tag{28}$$

Moreover, the filter parameter $K_{k+1}$ given by (27) minimizes the upper bound $\Sigma_{k+1|k+1}$.

**Proof** Note that the covariance matrices $P_{k+1|k}$ and $P_{k+1|k+1}$ can be rewritten as the functions of $P_{k|k}$ and $P_{k+1|k}$, respectively. Then, it is not difficult to verify that the condition (9) in Lemma 3 is satisfied.

Now, we are ready to deal with the terms of the right-hand side of (19). Considering the following elementary inequality

$$\left(\varepsilon^{\frac{1}{2}}\tilde{x}_{k+1|k}-\varepsilon^{-\frac{1}{2}}\hat{x}_{k+1|k}\right)\left(\varepsilon^{\frac{1}{2}}\tilde{x}_{k+1|k}-\varepsilon^{-\frac{1}{2}}\hat{x}_{k+1|k}\right)^T\ge0,$$

we can obtain the following inequality

$$\begin{aligned}&\tilde{x}_{k+1|k}\hat{x}_{k+1|k}^T+\hat{x}_{k+1|k}\tilde{x}_{k+1|k}^T\\ &\le\varepsilon\tilde{x}_{k+1|k}\tilde{x}_{k+1|k}^T+\varepsilon^{-1}\hat{x}_{k+1|k}\hat{x}_{k+1|k}^T\end{aligned}$$

with $\varepsilon>0$ being a scalar, which yields

$$\begin{aligned}&E\left\{x_{k+1}x_{k+1}^T\right\}\\ &\le E\left\{(1+\varepsilon)\,\tilde{x}_{k+1|k}\tilde{x}_{k+1|k}^T+\left(1+\varepsilon^{-1}\right)\hat{x}_{k+1|k}\hat{x}_{k+1|k}^T\right\}\\ &=(1+\varepsilon)\,P_{k+1|k}+\left(1+\varepsilon^{-1}\right)\hat{x}_{k+1|k}\hat{x}_{k+1|k}^T.\end{aligned} \tag{29}$$

Then, the last term of the right-hand side of (19) can be determined as

$$\begin{aligned}&K_{k+1}(J_{k+1}+V)K_{k+1}^T\\ &\le K_{k+1}\left[\check{\Xi}_{k+1}\circ\left(C_{k+1}M_{k+1|k}C_{k+1}^T\right)+V\right]K_{k+1}^T\end{aligned} \tag{30}$$

where where

$$M_{k+1|k}:=(1+\varepsilon)\,P_{k+1|k}+\left(1+\varepsilon^{-1}\right)\hat{x}_{k+1|k}\hat{x}_{k+1|k}^T.$$

It then follows from (19) and (30) that

$$\begin{aligned}&P_{k+1|k+1}\\ &\le\left(I-K_{k+1}\bar{\Xi}_{k+1}C_{k+1}\right)P_{k+1|k}\\ &\quad\times\left(I-K_{k+1}\bar{\Xi}_{k+1}C_{k+1}\right)^T+K_{k+1}\\ &\quad\times\left[\check{\Xi}_{k+1}\circ\left(C_{k+1}M_{k+1|k}C_{k+1}^T\right)+V\right]K_{k+1}^T\end{aligned} \tag{31}$$

Combining (23), (24) and (31), we can show that the condition (10) in Lemma 3 is satisfied. Therefore, it follows directly from Lemmas 2-3 that

$$P_{k+1|k+1}\le\Sigma_{k+1|k+1}.$$

Having determined the upper bound $\Sigma_{k+1|k+1}$, we are now ready to show that the filter parameter given by (27) is optimal in the sense that it minimizes the upper bound $\Sigma_{k+1|k+1}$. Taking the partial derivative of (24) with respect to $K_{k+1}$ and letting the derivative be zero, we have

$$\begin{aligned}&\frac{\partial\mathrm{tr}\left(\Sigma_{k+1|k+1}\right)}{\partial K_{k+1}}\\ &=-2\left(I-K_{k+1}\bar{\Xi}_{k+1}C_{k+1}\right)\Sigma_{k+1|k}C_{k+1}^T\bar{\Xi}_{k+1}\\ &\quad+2K_{k+1}\left[\check{\Xi}_{k+1}\circ\left(C_{k+1}\Phi_{k+1|k}C_{k+1}^T\right)+V\right]\\ &=0.\end{aligned} \tag{32}$$

From (32), and through straightforward algebraic manipulations, the optimal filter parameter $K_{k+1}$ can be determined as follows:

$$\begin{aligned}&K_{k+1}\\ &=\Sigma_{k+1|k}C_{k+1}^T\bar{\Xi}_{k+1}\Big[\bar{\Xi}_{k+1}C_{k+1}\Sigma_{k+1|k}C_{k+1}^T\bar{\Xi}_{k+1}\\ &\quad+\check{\Xi}_{k+1}\circ\left(C_{k+1}\Phi_{k+1|k}C_{k+1}^T\right)+V\Big]^{-1}\end{aligned} \tag{33}$$

Obviously, the filter parameter $K_{k+1}$ in (33) is identical to (27). To this end, the optimal filter gain $K_{k+1}$ is designed in the sense of minimizing the upper bound $\Sigma_{k+1|k+1}$ for the filtering error covariance and, therefore, the proof of this theorem is complete.

**Remark 5** At each sampling instant, the filter parameter $K_{k+1}$ is designed in Theorem 1 to minimize the upper bound of filtering error covariance. The consideration of the multiple missing measurements constitutes the main difference between our work and the work of [24]. In our main results, the constants $\vartheta_k^i$ $(i=1,2,\ldots,m)$ are there for the missing measurements where all sensors are allowed to have different missing probabilities. Furthermore, the proposed filter is derived in terms of the solutions to two Riccati-like difference equations, which is recursive and therefore suitable for online applications.

## IV. An illustrative example

Consider the following nonlinear system with missing measurements:

$$\begin{cases} x_{k+1} = f(x_k) + D_k\omega_k \\ y_k = \Xi_k C_k x_k + \nu_k \end{cases}$$

where

$$\begin{aligned} f(x_k) &= \begin{bmatrix} 0.8x_{1,k} + x_{1,k}x_{2,k} \\ 1.5x_{2,k} - x_{1,k}x_{2,k} \end{bmatrix}, \\ D_k &= \begin{bmatrix} 0.06 \\ 0.03 + 0.5e^{-5k} \end{bmatrix}, \\ C_k &= \begin{bmatrix} 0.85 & 0 \\ 0 & -1.5 \end{bmatrix} \end{aligned}$$

and $x_k = \begin{bmatrix} x_{1,k} & x_{2,k} \end{bmatrix}^T$ is the state vector with $x_{i,k}$ $(i = 1, 2)$ being the $i$-th element of the system state, $\omega_k \in R$ and $\nu_k \in R^2$ are zero-mean Gaussian white noises with covariances $0.5$ and $0.02I_2$, respectively.

In the simulation, set the initial value of estimation as $\hat{x}_{0|0} = \bar{x}_0 = \begin{bmatrix} 0.8 & 0.2 \end{bmatrix}^T$ and $\Sigma_{0|0} = 10I$. Assume that $\bar{\Xi}_k = \text{diag}\{0.95, 0.90\}$. The other parameters are chosen as $B_k = \text{diag}\{0.1, 0.2\}$, $L_k = 0.1I_2$, $\gamma_k = 0.005$, and $\varepsilon = 0.35$. By solving (23) and (24), the filter parameter can be obtained recursively and the simulation results are shown in Figs. 1-4. Here, MSE-$i$ $(i = 1, 2)$ denotes the mean square error (MSE) for the estimation of the state.

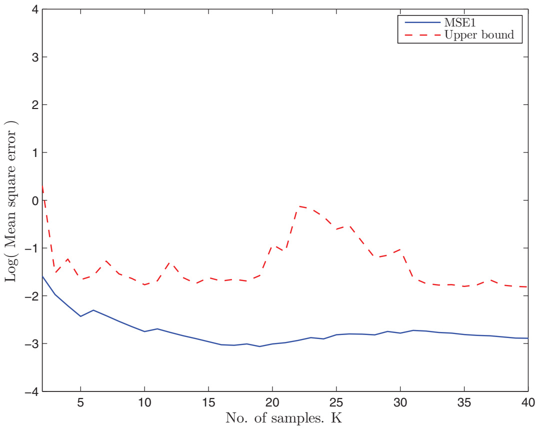

Fig. 1. MSE1 and its upper bound

In the figures, Figs. 1-2 show the upper bounds $\Sigma^{11}_{k|k}$ and $\Sigma^{22}_{k|k}$ as well as the MSE for the states $x_{1,k}$ and $x_{2,k}$, which confirm that the MSE stay below their upper bounds. The trajectories of the actual states $x_{i,k}$ and their estimates $\hat{x}_{i,k}$ $(i = 1, 2)$ are plotted in Figs. 3-4, which illustrate that the

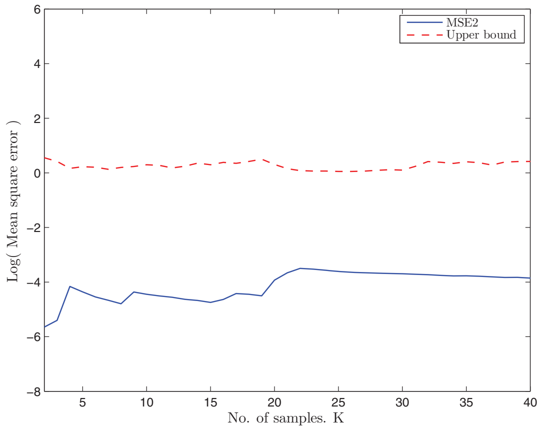

Fig. 2. MSE2 and its upper bound

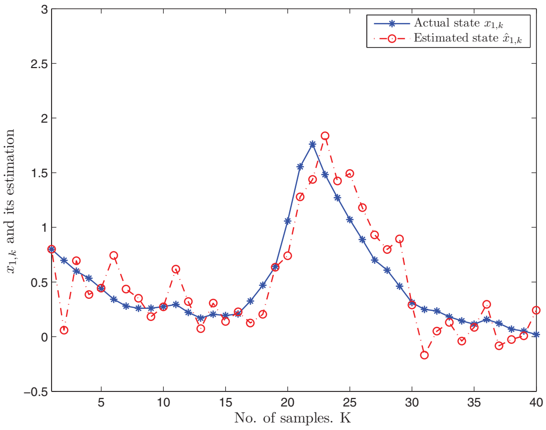

Fig. 3. The actual state $x_{1,k}$ and its estimation $\hat{x}_{1,k}$

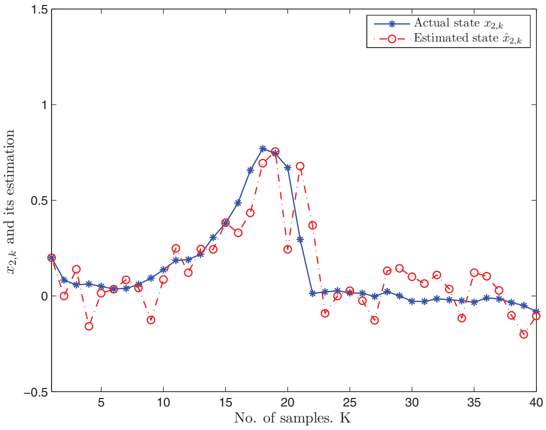

Fig. 4. The actual state $x_{2,k}$ and its estimation $\hat{x}_{2,k}$

presented scheme can perform well to estimate the system states.

## V. Conclusions

In this paper, the finite-horizon filter design problem has been investigated for a class of time-varying nonlinear systems with missing measurements. A series of mutually independent random variables that obeys Bernoulli distribution has been introduced to describe the missing measurement phenomenon. A filter has been designed to guarantee an optimized upper bound on the filtering error covariance by means of solving two Riccati-like difference equations. Finally, a numerical example has been provided to illustrate the effectiveness of the main results. Further research topics include the extension of the main results to the recursive filtering problem for general nonlinear stochastic systems, to the finite-horizon $H_\infty$ filtering problem with fading measurements, and so on.

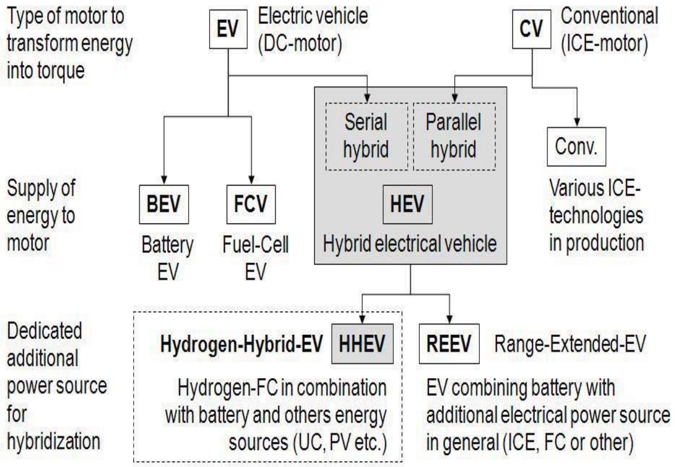
*Abstract*—**This paper investigates the design of an optimal energy recovery system for a hydrogen hybrid electric vehicle to allow increased range. The proposed system includes two different energy recovery sub-systems. These are; a regenerative braking sub-system and an active suspension sub-system. A dynamic model of this optimal energy recovery sub-system is implemented in MATLAB/Simulink$^{TM}$ and integrated with a hydrogen hybrid electric vehicle model to investigate the effect of the optimal energy recovery mechanism. The simulation results indicate the energy recovery and hence, lead to the extended range capabilities.**

***Keywords – Hydrogen hybrid vehicles, Regenerative braking, Active suspension system, Energy recovery***

## I. INTRODUCTION

The increasing global demand of fuels together with  and green house gas (GHG) environmental concerns, have progressively leads to the global trend towards low-emission and fuel efficient vehicles in recent years [1].



Type of motor to transform energy into torque
EV
Electric vehicle (DC-motor)
CV
Conventional (ICE-motor)
Serial hybrid
Parallel hybrid
Conv.
Supply of energy to motor
BEV
Battery EV
FCV
Fuel-Cell EV
HEV
Hybrid electrical vehicle
Various ICE-technologies in production
Dedicated additional power source for hybridization
Hydrogen-Hybrid-EV
HHEV
Hydrogen-FC in combination with battery and others energy sources (UC, PV etc.)
REEV
Range-Extended-EV
EV combining battery with additional electrical power source in general (ICE, FC or other)

Fig.1 Classification of HEV systems

Several variations and definitions have recently been under some scrutiny for use in alternative car concepts (see Fig.1). Among these vehicles, renewable hydrogen hybrid electric vehicles (HHEV) are considered to be one of the potential alternative candidates to replace conventional fossil fuelled internal combustion engine vehicles. Renewable hydrogen fuel cell vehicles are able to provide better fuel economy and comparatively reduced environmental pollution [2]. By incorporating energy recovery mechanisms, improved performance through energy recovery can be achieved [3]. Energy loss can also be minimized and fuel consumption rate be kept low. In such circumstances, an efficient economic fuel cell vehicle can be realised [3], [4]. The utilization of energy recovery systems makes the hydrogen fuel cell vehicles more attractive by better utilising the on board storage capacity for hydrogen, through raised energy efficiency. Model-based simulation has been used to assist in making an assessment of the benefits from such a system and can be used in exploring further options for improving energy efficiency.

Recent research efforts show that the energy recovery via an active suspension system in hydrogen hybrid electric vehicle may play a part in improving efficiency and extended range capabilities [5], [6]. Energy recovery suspension can achieve a damping function and energy recovery by changing the suspension input vibration produced by road roughness into electrical energy, so removing energy and effecting damping. The control structure of a plausible suspension system is shown in Fig.2. The control unit will detect the available energy supply from the suspension subsystem via the sensors circuit. The recovered energy will then be stored in the vehicle's main electrical energy storage (ESS) such as a battery, to be utilised subsequently to extend the range of the electric vehicle.

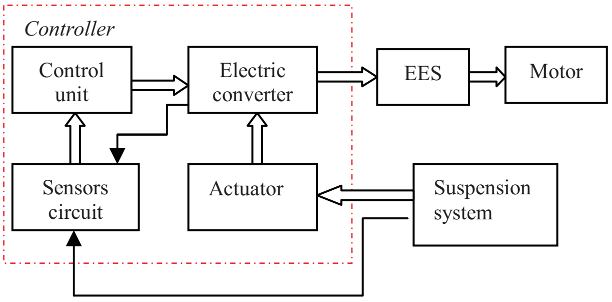


Fig.2 Control operation of a suspension system

978-1-4673-1560-9/12/$31.00 ©2012 IEEE

Results from previous research show that, significant amount of energy can also be recovered by the integration of the regenerative braking mechanism [4]. Further research effort should focus on the development of a systematic and integrated energy recovery system to recover as much kinetic energy as possible, while maintaining suitable power flows in the other subsystems and effecting a suspension function. To this end, several researchers have developed many different configurations of energy recovery mechanisms to continuously recover energy otherwise dissipated, that results from road irregularities, vehicle acceleration, and braking; see for example [7]-[12]. This recovered energy can be used to reduce fuel consumption.

This work addresses the issues relating to the development of a new mechanism for optimal energy recovery. The main purpose of the paper is to employ a simulation model of a renewable hydrogen fuel cell vehicle together with an optimal energy recovery system (OERS) to carry out simulation analysis to investigate the effect of the OERS.

## II. Energy Recovery Systems for HEV

The energy efficiency and driving range of HHEV system can be increased through the development and incorporation of OERS. Many different types of energy recovery system have been developed over the last two decades. These range from electro-hydraulic braking systems (EHBS) to regenerative shock absorbers [13]-[18].

EHBS can be configured in either series or parallel regenerative mode. In a series configuration, the hydraulic control unit manages the brake cylinder pressures, as well as the front-rear axle brake balance. It requires active brake management to achieve total braking to all four wheels. However, it should be noted that in most modern hybrid electric vehicles the regenerative braking system is applied only on the drive wheel, consequently the system has to use thermal/friction braking systems at the same time, to equilibrate the braking. Parallel configuration is less complex because the thermal brakes are used along with energy recovery by the reversible motor/generator. Front and rear brake balance is retained because the thermal brakes are in use during the entire braking event. The amount of energy captured by a parallel regenerative braking system is thus less than from a series system [19].

Hydraulic power assist is another way of managing the energy usage. In the hydraulic power assist, when the driver steps on the brake, the vehicle's kinetic energy is used to power a reversible pump, which sends hydraulic fluid from a low pressure accumulator into a high pressure accumulator. The pressure is created by nitrogen gas in the accumulator, which is compressed as the fluid is pumped into the space the bagged or isolated gas formerly occupied. This slows the vehicle and helps bring it to stop. The fluid remains under pressure in the accumulator until the driver pushes the accelerator again, at which point the pump is reversed and the pressurized fluid is used to accelerate the vehicle.

Regenerative shock absorber mechanisms are a recent development for energy recovery and are essentially regenerative suspension systems technologies. In such regenerative suspension systems, the function is, as in a conventional automotive shock absorber, mechanisms to dampen suspension movements to produce a controlled action that keeps the tire firmly on the road and filters road irregularities for comfort and vehicle integrity. This is normally done by converting the kinetic energy into heat energy, which is then dissipated through the hydraulic oil and cylinder by heat transfer to atmosphere. The power generating shock absorber converts this kinetic energy into electricity through the use of a linear electric generator or other device. The electricity generated by each power generating shock absorber stroke (see Fig.3) can then be combined with electricity from other power generation systems such as regenerative braking and stored in the vehicle's energy storage systems [20].

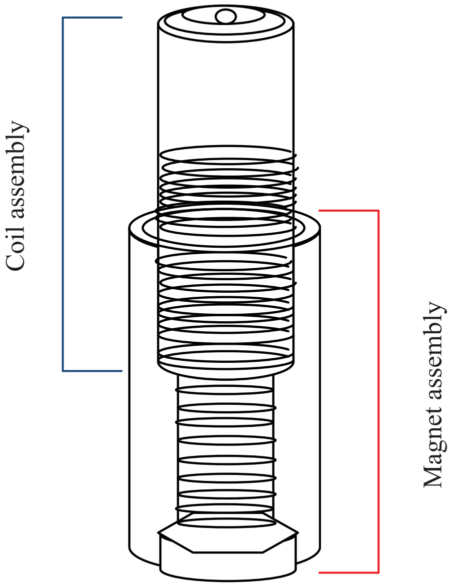

Fig.3 Shock absorbers

For the proposed OERS system, two different energy recovery mechanisms have been considered. These are; the suspension energy recovery mechanism and regenerative braking subsystem. The combined energy recovery sources (suspension energy recovery mechanism and regenerative braking) in the HHEV system may provide a more viable solution if increased capital costs can be rendered economic. The suspension energy recovery mechanism will recover some energy from suspension system and through regeneration from braking, the vehicle is allowed to recapture and store a part of the kinetic energy as opposed to wasting it as heat. Regenerative braking and suspension both essentially convert kinetic energy back into usable energy. Hence, they will be most beneficial in circumstances where most energy is otherwise lost.

## III. OERS Model

In order to develop an optimal energy recovery system model, it is hypothesised that utilization of a regenerative braking system and an active energy recovery suspension processes in a single system, make the proposed optimal energy recovery system more attractive from an energy system point of view.

*Regenerative braking system:* In recent literature, hybrid electric vehicle systems, regenerative braking is applied only on the drive wheels, therefore a standard front wheel-drive configuration [21], [22] is adopted in this paper. The regenerative braking operation can be described by the following equations.

The braking force required $F_{req}$ is given by;

$$F_{req} = F_{acc} - F_{roll} - F_{drag} - F_{hill} \qquad (1)$$

Where $F_{acc}$ is the force required to give the rate of change of velocity (i.e., acceleration/deceleration), $F_{roll}$ the rolling resistance force, $F_{drag}$ is the aerodynamic drag, $F_{hill}$ is the hill climbing force.

The power required to slow the vehicle $P_{req}$ is calculated by;

$$P_{req} = F_{req} v \qquad (2)$$

Where $v$ is the vehicle velocity.

$P_{req}$ is the total power required for the front and rear axles. Thus,

$$P_{req} = P_f + P_r \qquad (3)$$

Where $P_f$ and $P_r$ are the power provided by the front and rear wheels respectively. It should be noted that $P_f > P_m$ due to the efficiency of the motor sub-system, where $P_m$ is the motor electric power and is given by;

$$P_m = \eta_m . P_f \qquad (4)$$

Where $\eta_m$ is the efficiency of the motor and is calculated by;

$$\eta_m = \tau_m \omega_m / (\tau_m \omega_m + k_1 \tau_m^2 + k_2 \omega_m + k_3 \omega_m^3 + k_s) \qquad (5)$$

Where $\tau_m$ is the motor braking torque, $\omega_m$ is the motor angular speed, $k_1, k_2$ and $k_3$ are the material losses coefficients. $k_s$ is the constant losses that apply at any velocity

The power that charges the battery $P_{ch}$ is given by;

$$P_{ch} = P_m - P_{av} \qquad (6)$$

When $P_{ch} < 0$ it becomes the discharge power, where $P_{av}$ is the average power of the accessories, i.e., the electric power needed to run the other electrical systems. While the HHEV is in motion; when braking is applied, a certain amount of power is dissipated into the battery. In this paper an internal resistance battery model [5] is adopted, which characterizes the battery with a voltage source and an internal resistance.

Let the current $I$ be flowing into the battery, so the charge power of the battery can be obtained as;

$$P_{ch} = EI + I^2 R \qquad (7)$$

Where $E$ is the open circuit voltage, and it changes with the state of charge ( $S$ ) of the battery, $R$ is the internal resistance of the battery. Now, the charge current $I$ is obtained by solving equation (7) and is given by;

$$I = (-E + \sqrt{E^2 + 4RP_{ch}}) / 2R \qquad (8)$$

and $(S)$ is represented as follows;

$$(S) = (S_0) + \Delta t \times I . C_P^{-1} \qquad (9)$$

Where $(S_0)$ is the battery initial state of charge, $\Delta t$ is the sampling time and $C_P$ is the Peukert capacity.

The regenerated power of the battery is calculated as;

$$P_{regen} = P_{ch} - I^2 R \qquad (10)$$

With the regenerated energy efficiency $\eta_{regen}$ defined as;

$$\eta_{regen} = \frac{\int P_{regen}}{\int P_{req}} \qquad (11)$$

From the above regenerative braking system (RGBS) model it is clear that the amount of regenerated brake energy depends on multiple factors in HHEV.

*Suspension energy recovery system*: Energy recovery suspension processes can achieve a significant amount of energy recovery by converting suspension vibration damping required for road roughness, into electrical energy. Design studies of suspension energy recovery systems for hybrid electric vehicles have been conducted recently by several researchers, see for example, [3], [6]. Hybrid electric vehicle configuration with active suspension systems would allow the recovery of energy and hence, lead to the extended range capabilities. The purpose of a suspension system is to support the vehicle body, damp vibration and increase ride comfort. Currently, there are three different types of suspension systems used in automobile industry: passive, semi-active and active [6]. The traditional passive suspensions use springs and dampers to absorb the oscillation while in active cases the suspension is controlled by an external controller. Semi-active suspensions include devices such as springs and shock absorbers together with other systems such as hydro-pneumatic and electromagnetic suspension. On the one hand, the use of semi-active/active suspension achieves a better isolation performance for various vibration modes and improves the riding comfort, but on the other hand, they increase the cost, weight and energy consumption of the car. The suspension energy recovery mechanism developed here is expected to recovery some energy from the suspension system to improve the energy efficiency. The dynamic model with seven degree of freedom (7-DOF); four wheel suspension systems can be expressed using differential equations [5]. Fig. 4 shows a simplified version of a suspension system for a complex full car model.

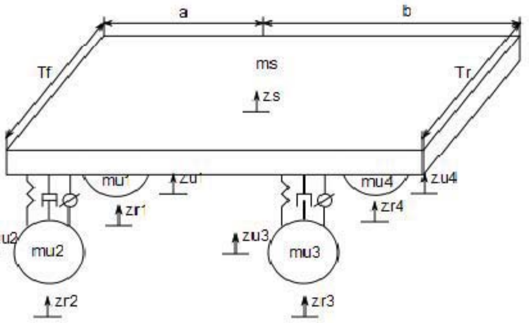

Fig.4. Simplified version of a suspension system for a complex full car model

There are roll, pitch and vertical displacement of sprung mass and four unsprung mass are included. The dynamic model is divided into seven main parts:

Bouncing of the sprung mass

$$\begin{aligned} m_s\ddot{Z}_s = & -b_f\left(\dot{Z}_{s_1}-\dot{Z}_{u_1}\right)-bf\left(\dot{Z}_{s_2}-\dot{Z}_{u_2}\right)-br\left(\dot{Z}_{s_3}-\dot{Z}_{u_3}\right) \\ & -br\left(\dot{Z}_{s_4}-\dot{Z}_{u_4}\right)-kf\left(Z_{s_1}-Z_{u_1}\right)-kf\left(Z_{s_2}-Z_{u_2}\right) \\ & -kr\left(Z_{s_3}-Z_{u_3}\right)-kr\left(Z_{s_4}-Z_{u_4}\right)+u_1+u_2+u_3+u_4 \end{aligned} \tag{12}$$

Pitching of the sprung mass

$$\begin{aligned} I_p\ddot{\theta}_s = & -b_f a\left(\dot{Z}_{s_1}-\dot{Z}_{u_1}\right)-b_f a\left(\dot{Z}_{s_2}-\dot{Z}_{u_2}\right)-b_r b\left(\dot{Z}_{s_3}-\dot{Z}_{u_3}\right) \\ & +b_r b\left(\dot{Z}_{s_4}-\dot{Z}_{u_4}\right)-k_f a\left(Z_{s_1}-Z_{u_1}\right)+k_f a\left(Z_{s_2}-Z_{u_2}\right) \\ & +k_r b\left(Z_{s_3}-Z_{u_3}\right)+k_r b\left(Z_{s_4}-Z_{u_4}\right)+au_1+au_2-bu_3-bu_4 \end{aligned} \tag{13}$$

Rolling of the sprung mass

$$\begin{aligned} I_r\ddot{\varphi}_s = & -b_f T_f\left(\dot{Z}_{s_1}-\dot{Z}_{u_1}\right)-b_f T_f\left(\dot{Z}_{s_2}-\dot{Z}_{u_2}\right)-b_r T_r\left(\dot{Z}_{s_3}-\dot{Z}_{u_3}\right) \\ & +b_r T_r\left(\dot{Z}_{s_4}-\dot{Z}_{u_4}\right)-k_f T_f\left(Z_{s_1}-Z_{u_1}\right)+k_f T_f\left(Z_{s_2}-Z_{u_2}\right) \\ & -k_r T_r\left(Z_{s_3}-Z_{u_3}\right)+k_r T_r\left(Z_{s_4}-Z_{u_4}\right)+T_f u_1-T_f u_2+T_r u_3-T_r u_4 \end{aligned} \tag{14}$$

Vertical direction for each wheel

$$m_{uf}\ddot{Z}_{u_i}=b_f\left(\dot{Z}_{s_i}-\dot{Z}_{u_i}\right)+k_f\left(Z_{s_i}-Z_{u_i}\right)-k_{tf}Z_{u_i}-u_i+k_{tf}Z_{r_i} \tag{15}$$

with $i=1,2,3,4$

where;

$$Z_{s_1}=T_f\varphi_s+a\theta_s+Z_s\,,\ \dot{Z}_{s_1}=T_f\dot{\varphi}_s+a\dot{\theta}_s+\dot{Z}_s$$

$$Z_{s_2}=-T_f\varphi_s+a\theta_s+Z_s\,,\ \dot{Z}_{s_2}=-T_f\dot{\varphi}_s+a\dot{\theta}_s+\dot{Z}_s$$

$$Z_{s_3}=-T_r\varphi_s-b\theta_s+Z_s\,,\dot{Z}_{s_3}=-T_r\dot{\varphi}_s-b\dot{\theta}_s+Z_s$$

$$Z_{s_4}=-T_r\varphi_s-b\theta_s+Z_s\,,\ \dot{Z}_{s_4}=-T_r\dot{\varphi}_s-b\dot{\theta}_s+\dot{Z}_s$$

where $Z_s$ is the vertical displacement, $Z_{u_i}$ $(i=1,2,3,4)$ is the vertical displacement of each wheel, $\theta_s$ pitch angle and $\varphi_s$ roll angle.

So far, a regenerative braking system model and a suspension system for a complex full car model have been established. These models are then used for the design of a combined OERS system to improve HHEV performance.

The combined OERS system is implemented in MATLAB/Simulink$^{TM}$ and incorporated into a vehicle simulator [5] to analysis the effect of the integration of the OERS system. In the following section of the paper discusses results from the OERS system developments.

## IV. Results and Discussion

The simulation results show that by using this combined optimal energy recovery mechanism, a considerable amount of energy can be recovered. For illustrative purposes, example simulation results are shown here. For this simulation, the New European drive cycle (NEDC) (see Fig.5) is used here and the suspension system parameters are listed in Table 4.1.

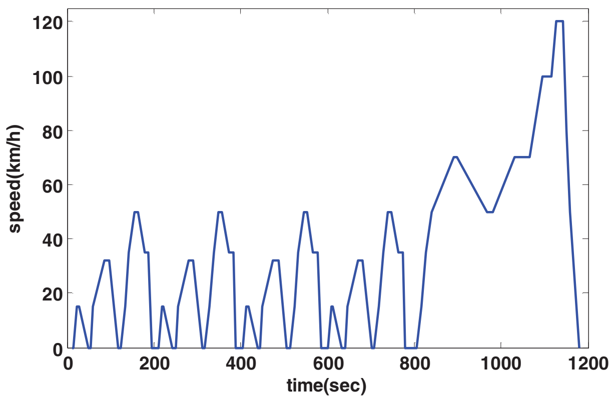

Fig.5 New European  Drive cycle

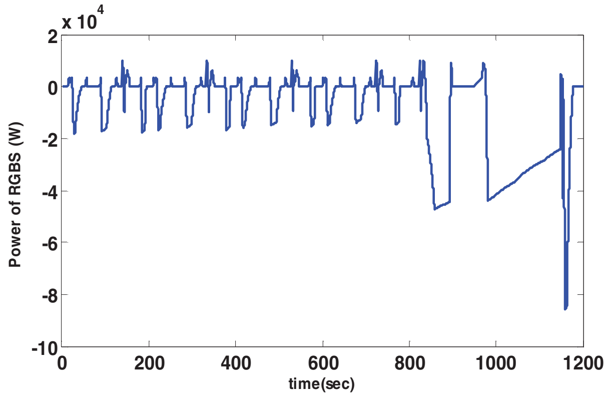

Fig.6 Power of RGBS energy recovery

Table 4.1: Suspension system parameters

| Symbol | Quantity | Unit |
|---|---|---|
| Suspension system parameters | | |
| $m_s$ | 464 | Kg |
| $m_u$ | 35 | Kg |
| $K_s$ | 16812 | N/m |
| $K_t$ | 190000 | N/m |
| $b_s$ | 1000 | N/m |
| $b_t$ | 1000 | N/m |

where $m_s$ is the mass of a vehicle, $m_u$ is the mass of a wheel components, $K_s$ is the spring stiffness, $K_t$ is the tire stiffness, $b_s$ is the damper coefficient, and $b_t$ is the tire damping coefficient.

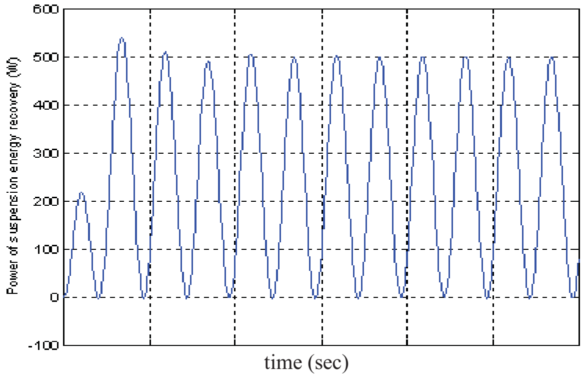

Fig.7 Power of suspension energy recovery

Suppose, the energy recovered by the use of the suspension energy recovery mechanism is used to produce hydrogen, then the average hydrogen production rate is about $4\times10^{-3}kgh^{-1}$ (see Fig.8).

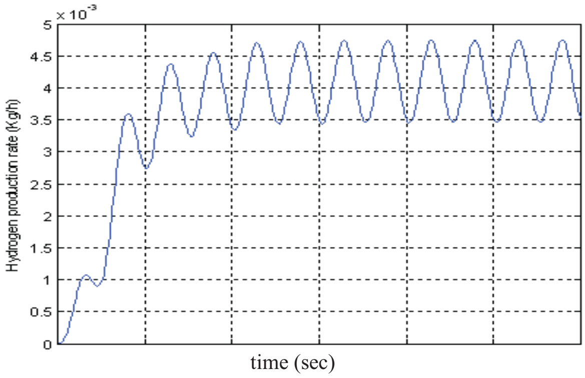

Fig.8 Hydrogen production rate from the suspension energy recovery mechanism

Fig. 6 and 7 shows the power of RGBS energy recovery and power of suspension energy recovery respectively. From the results it is clearly shown that the RGBS recover more energy than the suspension energy recovery system. However, it should be noted that the total energy recovered by the use of OERS is higher than using only the suspension recovery mechanism or RGBS (see Fig.9 and 10). In Fig. 9 the total energy recovery by the OERS is shown. Figure 10 shows the enlarged view of compared responses of Fig.6 and 9 for the first 30 sec in order to clearly show the power of OERS (solid line) and RGBS (dashed line).

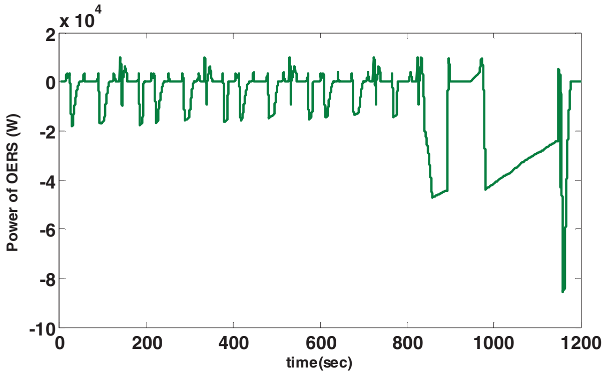

Fig.9 Power of OERS system

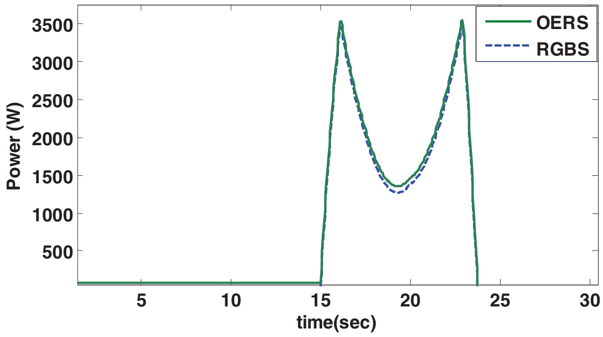

Fig.10 Comparison of power of OERS and RGBS

## V. CONCLUDING REMARKS

In this paper, an investigation of the development of an optimal energy recovery system for a renewable hydrogen fuel cell vehicle is carried out. A dynamic model of a regenerative braking system and an active suspension energy recovery system has been developed and combined as a single energy recovery mechanism. This optimal energy recovery subsystem is implemented in MATLAB/Simulink$^{TM}$. The model is then incorporated into a vehicle simulator to analysis the effect of the integration of the energy recovery mechanism. The results show that by using this mechanism, significant amount of energy can be recovered. It is expected that the modelling will provide a suitable platform for investigating the effects of system architecture and vehicle drive cycles analysis.

***Abstract*—The Best Linear Approximation (BLA) is a linearisation of the transfer characteristics of a nonlinear system in a least squares sense. The BLA is known to depend on the statistical properties of the input signal used to identify it. The theory for Gaussian input sequences has been known for several years, but the corresponding theory for binary input sequences has only recently been developed. In this paper, experiments on a physical electronic Wiener system, aimed at verification of predictions made for the differences between BLA's estimated using Gaussian sequences and those estimated using binary sequences, are described. The results were found to be a good match with the theory but difficulties encountered during the experiment highlight a need for further work in extending the discrete-time theory to the continuous-time domain.**

## I. Introduction

In system identification, the frequency response function or the impulse response of a system contains information about the system. Based on this information, one can model, make prediction and control the system to produce desired behaviour. All systems are nonlinear to some extent, and in some systems the nonlinearity plays a significant role. Even so, linearising a nonlinear system has merits in modelling and control, and the Best Linear Approximation (BLA) [1–5], which is a linear model minimising the expected value of mean squared difference between the actual output of the system and the modelled output is particularly useful for this. The BLA however, depends on the power and amplitude distribution of the excitation signals used to identify it [6]. This paper verifies the theory developed by Wong et al. [6] for binary input signals through experiments on a physical electronic system with a linear low-pass filter and a cubic nonlinearity in a Wiener configuration.

## II. Experiment Setup

The system was set up using the equipment listed below, and following the system schematic shown in Figure 1. The HP VXI mainframe was connected to a desktop computer with the MATLAB software. Data analysis was performed through MATLAB.

### A. List of equipment

- HP E1401B VXI mainframe with:
  - VXI-MXI-2 interface card
  - 2 × HP E1430A 10 MSa/s 23-bit ADCs, with filtering and memory (henceforth referred to as 'acquisition card')
  - HP E1445A arbitrary function generator card
- Desktop computer with PCI-MXI-2 interface card
- Non-inverting pre-buffer with AD8610A op-amp
- Non-inverting post-buffer with TL071CP op-amp
- 2 × 50 Ω matched impedance buffers
- RC filter circuit with changeable resistors and capacitors
- 50 Ω matched impedance measurement buffers
- Pre-built cubic nonlinearity circuit
  - based on AD532JH four-quadrant multipliers
- Tektronix TDS 2001C Oscilloscope
- ±12 V and ±15 V power supplies
- A 1.5 nF capacitor with either 2.7 kΩ, 27 kΩ or 110 kΩ resistors in the RC filter,
  - giving cut-off frequency values of $f_{\text{co}} = 39.3\,\text{kHz}$, 3.93 kHz and 0.965 kHz respectively.

### B. Methodology

The objective is to verify theoretical difference between the BLA's obtained from the use of Maximum Length Binary Sequences (m-sequences) [7], and from Gaussian signals, more specifically random phase multisines [2]. The linearity was a simple RC filter circuit, and the nonlinearity was a static cubic power function. Three sets of experiments were performed, each with a different combination of time constants for the linearity. The resistor values used were 2.7 kΩ, 27 kΩ and 110 kΩ. The capacitor value was fixed at 1.5 nF, for a reason which will be explained in Section II-D.

Table I lists parameters and their values used in the experimental work. Both types of input were subjected to supersampling (see Section II-D). However, the bandwidth of the multisine was set equal to the clock frequency of the binary

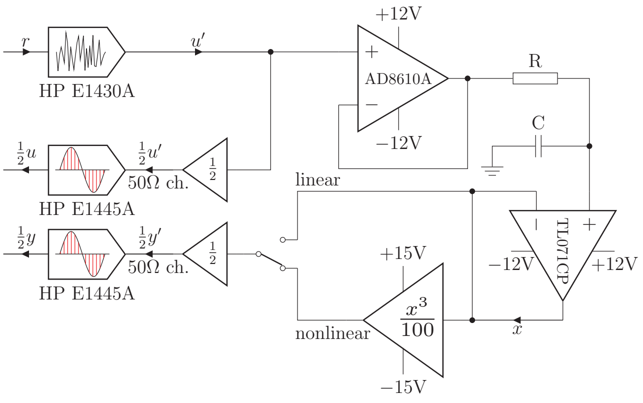

Figure 1. System schematic

sequence. This was performed so that after downsampling (also see Section II-D) at the measurement, both types of signal will have identical bandwidth and the spectral ‘whiteness’ of the two signal types could be preserved. The whiteness of the input spectrum constitutes one of the assumptions of the original discrete time BLA theory in Wong et al. [6].

The general procedure of data collection of the experiment for both the linear and nonlinear cases was as follows:

1) Generate the reference signal $r$, either:
   a) a discrete random-phase multisine for the Gaussian case, or:
   b) a Maximum Length Binary Sequence of period $N_{\text{base}} = 511$ samples for the binary case.
2) Realise the periodic signal using the HP E1445A arbitrary function generator card. The excitation is uninterrupted and continuously turned on from this point onwards.
3) Pause for 5 seconds so that transient effects in the measurements are expected to be negligible.
4) Initiate measurements with the acquisition cards and collect $P$ periods of data. The measurement intervals are internally synchronised with the generator.
5) Due to internal attenuation of the matched impedance buffers, measurements are normalised by a factor of two to obtain $u$ and $y$ (in multiple periods).
6) Go to Step 1 and repeat for a different realisation of input until $M$ data sets of different input realisations are obtained.

Note that across the $M$ sub-experiments, the same input sequence realisation was never used twice.

### C. Robust non-parametric identification procedure

Given a set of input and output data from $M$ sub-experiments of independent input realisations, each with $P$ periods of steady-state measurements, robust estimator for the BLA is given as:

$$\hat{G}_{\text{BLA}}(\mathrm{j}\omega) = \frac{\sum_{m=1}^{M}\sum_{p=1}^{P} Y_{[m,p]}U^{\star}_{[m,p]}}{\sum_{m=1}^{M}\sum_{p=1}^{P} U_{[m,p]}U^{\star}_{[m,p]}} \tag{1}$$

where $U_{[m,p]}$ and $Y_{[m,p]}$ contain the $m^{\text{th}}$ sub-experiment and $p^{\text{th}}$ period of the measured input spectrum $U(\mathrm{j}\omega)$ and the measured output spectrum $Y(\mathrm{j}\omega)$. The $^{\star}$ symbol denotes complex conjugate. For reasons stated in II-D, the measured input spectrum for the binary excitation case, $U_{[m,p]}$ is taken as the reference input spectrum $R_{[m]}(\mathrm{j}\omega)$.

The estimator is robust against noise disturbances and is unbiased if input noise levels are small.

### D. Supersampling

The HP VXI system is capable of any sampling frequency up to and including 10 MHz. In the experiment, the measurements were oversampled by a factor of $\mu$ above the frequency of the binary sequence input $f_{\text{c}}$. The upper frequency of the bandwidth of the random phase multisine $f_{\text{w}}$ was set equal to $f_{\text{c}}$. The measurement data were then subjected to manual downsampling by the same factor $\mu$. This results in both input signal types having identical bandwidth. The supersampling and the subsequent downsampling were performed for two main reasons detailed in the next two subsections (Ringing and Overshoot; Anti-alias).

The RC filter has low-pass (smoothing) characteristics. To downsample (or subsample) the measurement, a location of the highest peak (or lowest trough) of the output signal was taken as the reference point. From this reference point onwards and backwards every $\mu^{\text{th}}$ sample was taken as an idealised zero-order-hold (ZOH) measurement, with the ZOH clock frequency a factor $\mu$ lower than the original sampling (hence a downsampling). The reference signal $r$ and the measured output $y$ were also aligned through this reference point, so that the peaks of the output after RC filtering would then occur directly after the switching points of the binary reference input. The procedure is more easily appreciated by referring to Figure 2 by comparing the reference input (dotted line) and the two red solid lines representing the original high frequency sampling and the subsequent downsampled and aligned ZOH data. If there were no ringing, overshoot, nonlinear effects or noise, this subsampling procedure would result in a perfect reconstruction of the behaviour of an ideal ZOH sampler according to discrete-time theory. This had been verified by simulation. This subsampling procedure is performed for both linear and nonlinear measurements. Since this procedure can only be reliably performed through the easily visible binary switching points, the same alignment amount and reference point time coordinate were used for the corresponding case with multisine input.

*Ringing and overshoot:* During testing with binary excitation signals, it was observed through the oscilloscope that

Table I
Table of parameters and settings

| Symbol | Description | Value (units) | |
|---|---|---|---|
| $f_s$ | Sampling frequency for the arbitrary waveform generator, and acquisition cards. The Nyquist frequency is then $f_s/2$. | 312.5 | kHz |
| $T_s$ | Sampling interval $= 1/f_s$. | 3.2 | µs |
| $\mu$ | Over-sampling ratio for m-sequences (see Section II-D). | 8 | |
| $f_c$ | Clock frequency of the m-sequences $(= f_s/\mu)$. | $39\tfrac{1}{16}$ | kHz |
| $T_b$ | Bit interval for the m-sequences $(= 1/f_c)$. | 25.6 | µs |
| $f_w$ | Bandwidth of the multisine sequence before downsampling $(= f_c = f_s/\mu)$. | $39\tfrac{1}{16}$ | kHz |
| $f_{aa}$ | Anti-aliasing filter cut-off frequency $\equiv 0.4 f_s$. This coupling with the sampling frequency value is internally enforced by the HP1430A acquisition cards. | 125 | kHz |
| $N_{\text{base}}$ | Base length of sequence after subsampling, (= length of a 9-tap m-sequence) | 511 | Sa$^\dagger$ |
| $N$ | Length of a data record $(= \mu N_{\text{base}})$. | 4088 | Sa$^\dagger$ |
| $P$ | Number of periods measured (linear case; nonlinear case). | 12; 4 | |
| $M$ | Number of independent realisations (linear case; nonlinear case). | 5; 16 | |
| $V_{\text{rms}}$ | RMS voltage of the input signals. | 1.5 | V |

$^\dagger$Sa = samples

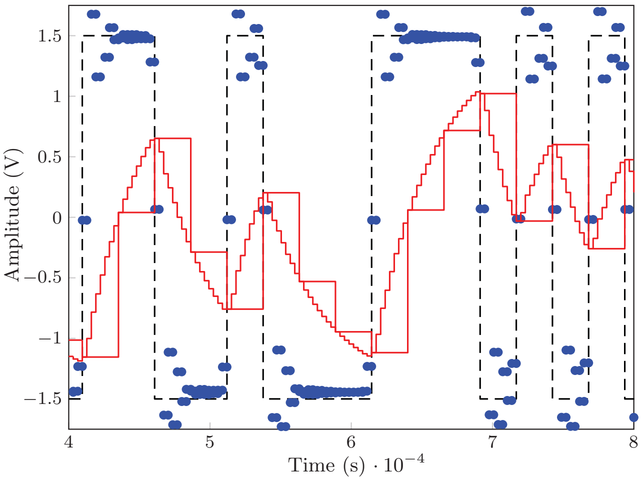

Figure 2. The use of supersampling and subsampling – Reference input (black dotted line), Measured input (blue dots), Measured output: a) supersampled and b) subsampled (red solid lines).

all operational amplifier (op-amp) based electronic buffers introduce high frequency oscillations in form of ringing to a varying extent. This is caused by non-ideal step-response characteristics when load or parasitic capacitances at output of op-amps introduce unintended poles in the transfer characteristics of the op-amps through feedback. The datasheets of many op-amps have step-response graphs which illustrate this.

In this experiment setup, the overshoots and undershoots were especially large, up to 20% with the pre-buffer due to the capacitive load at the RC circuit, even when a higher quality op-amp (with regards to its ability in driving capacitive loads) was used [8]. The overshoot depends on the load or parasitic capacitance hence the load capacitor $C$ of the RC circuit was fixed at 1.5nF for consistency.

Moreover, the HP E1430A acquisition cards themselves have significant overshoots that can be seen in the measurement data, although the oscilloscope suggested the actual acquisition inputs $u'$ and $y'$ were relatively free of such effects. This may be caused by the high order high cut-off frequency anti-aliasing filter having oscillatory step responses. The ringing at the measured input channel from an acquisition card can be seen in Figure 2. This phenomenon persisted with an Agilent 33120A waveform generator directly driving the acquisition cards, isolated completely from the system in question.

While the RC passively forms a low pass filter and is capable of minimising the effect of ringing from the pre-buffer, overshoot and ringing from the acquisition cards are inevitable. Due to the nature of sample-and-hold at the acquisition cards, the use of supersampling is necessary to obtain measurements of acceptable accuracy. The BLA theory developed is incapable of modelling in continuous time domain of such effects at the moment.

For multisine input sequences, there are no noticeable ringing or overshoot effects.

Because of the overshoot and ringing present in the measurement data from the HP E1430A acquisition cards, the signal sequence $u$ is no longer reliable and accurate representation of $u'$ in the m-sequence case. Henceforth in dealing with binary sequences, the reference signal $r$ is used as the basis for identification.

In addition, manual alignment of the measured input and output signals can be performed.

*Anti-alias:* It is necessary to minimise the effect of anti-aliasing filters on the measurements because of the use of the ideal reference signal $r$ instead of measured input $u$ in the case of binary excitations. In addition, the nonlinearity broadens the bandwidth of the output, which then may be interfered with by the anti-aliasing filter if action is not taken. Supersampling allows the internal anti-aliasing filter to be bypassed since the internal anti-aliasing filter of the HP E1430A acquisition cards have their cut-off frequencies $f_{\text{aa}}$ dependent upon the sampling frequency $f_{\text{s}}$ (see Table I). The combination of the specified low bandwidth of the multisine, the discrete nature of binary excitation signals and the low pass characteristics of RC mean that any real aliasing effect was negligible. It has been shown that broadening of spectrum due to nonlinearity would result in aliased components that are never coherent with the original input component [2, Theorem 3.21], hence the lack of anti-aliasing filter would only act as additional uncorrelated noise in the BLA measurement.

### *E. Linear measurements*

Measurements were performed to identify either a parametric or a non-parametric model for the linearity. The rms signal amplitudes for the Gaussian and binary signals were both set to 1.5 V. The non-parametric model was obtained using (1), and a parametric model was fitted where suitable using the iterative weighted nonlinear least squares procedure provided by ELiS in the *fdident* toolbox for MATLAB [9]. The weighting factors were proportional to the reciprocal of the variances at each frequency point. The isolation provided by the pre-buffer and post-buffer for the RC circuit introduced some additional linear dynamics, and hence suitable single pole models could not be fitted to the data. When a parametric model of order four is not sufficient to describe the transfer characteristics of the linearity in both the z-domain and the s-domain, the non-parametric model is used. This was the case for when the resistor value was 110 kΩ, and hence Figure 6 does not contain the results from the parametric model.

Figure 3 shows an example of the result of a non-parametric linearity identification. The noise variances indicate levels of exogenous additive noise from the environment whereas the total variances indicate the levels of nonlinear distortions plus environment noise. There is a discrepancy between the result obtained with multisine sequences and that obtained from m-sequences. This suggests input dependent nonlinear characteristics which include some effect from ringing oscillations.

As an example, for $R = 27\,\text{k}\Omega$ and with $C = 1.5\,\text{nF}$, the time constant $T_{\text{p}} = 27{\times}10^{3} \cdot 1.5{\times}10^{-9} = 4.05{\times}10^{-5}$ seconds. With a sampling interval $T_{\text{c}}$ given by $1/f_{\text{c}} = (39\,{}^{1}/_{16} \times 10^{3})^{-1}$ seconds, $T_{\text{c}}/T_{\text{p}} = 0.6321$, and therefore the theoretical transfer function is:

$$G(\text{z}) = \frac{\text{z}}{\text{z} - e^{-0.6321}} = \frac{\text{z}}{\text{z} - 0.5315}. \tag{2}$$

The parametric model identified for the m-sequence case with sampling time $T_{\text{c}}$ was:

$$\hat{G}(\text{z}) = \frac{0.01011(\text{z}+41.23)(\text{z}+0.05967)}{(\text{z}-0.5481)(\text{z}+0.01818)}. \tag{3}$$

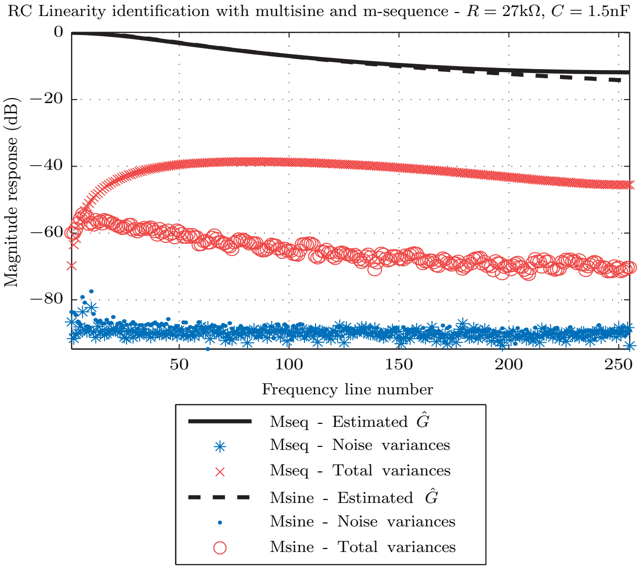

Figure 3. RC Linearity identification with op-amp based pre- and post-buffers. (To convert to frequency (Hz), line number should be multiplied by $f_{\text{s}}/(8 \times 511)$)

It can be seen that the estimated positive pole is very close to the theoretical value, but as noted above, the pre-buffer and the post-buffer to the RC circuit introduced some additional dynamics, with a negative zero and a negative pole very close to the origin, and a further negative zero that is so large that it can be regarded as a constant over the frequency range of interest.

Despite the fact that the system under test was linear, there were nonlinear distortions in both input cases and the level was higher for the binary input. This was due to to be non-linear effects from the unity-gain op-amp buffers, especially from the pre-buffer which had to drive the capacitive load. Ringing oscillations were especially noticeable with binary inputs (see II-D). If the buffers were not used, the nonlinear distortions disappear regardless of the input signal. However, due to current driving limitation of the signal generator and the capacitive load, there was unacceptable distortion of the realised input for the binary case, hence the buffers were necessary.

### *F. Nonlinear measurements and BLA theory*

The nonlinear measurements were obtained in a similar manner to the linear measurement case. The non-parametric BLA was obtained using (1).

To enable comparison with the theory, additional information is required. This includes the even higher order moments of the input signals, the signal power (or the rms value $V_{\text{rms}}$), the impulse response of the linearity and the polynomial coefficients of the nonlinearity. For the Gaussian case, the even order moments of $u$ (i.e., $\text{E}[u^{n}]$) were measured and averaged for a single experiment, for even $n$. For the binary case, $u$ was replaced by $r$ hence $\text{E}[r^{n}] = V_{\text{rms}}^{n}$. The impulse response of the linearity was taken from the parametric model

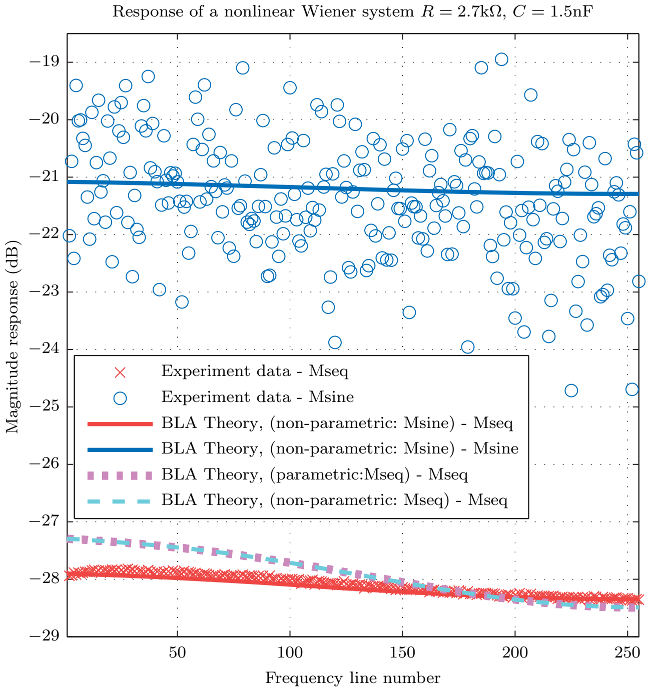

Figure 4. Experiment result of the identification of the BLA with Gaussian and binary inputs for an electronic Wiener system with non-ideal cubic nonlinearity and a RC linearity with $R = 2.7\text{k}\Omega$, $C = 1.5\text{nF}$ giving corner frequency $f_{\text{co}} = 39.3\text{kHz}$. (For conversion from frequency line number to Hz, see caption of Figure 3.)

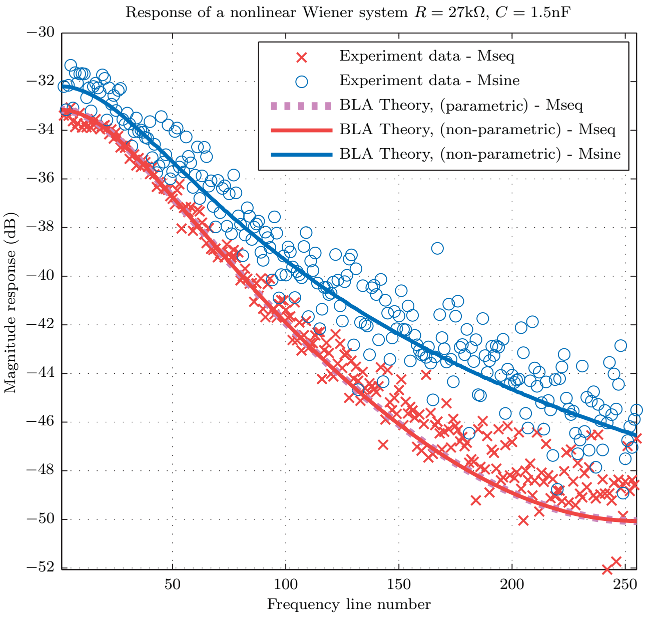

Figure 5. As Figure 4, but with $R = 27\text{k}\Omega$, giving corner frequency $f_{\text{co}} = 3.93\text{kHz}$.

if available, and the non-parametric model by inverse Fourier transform. Finally, the nonlinearity was identified by simple least squares polynomial regression performed on 20 periods of output data obtained from the nonlinearity with a multisine excitation as a direct input to the nonlinearity. The polynomial fitted to the nonlinearity was:

$$\begin{aligned} \text{f}_{\text{NL}}(x) = 0.01088x^3 - 0.001356x^2 \\ +0.008169x + 0.05816. \end{aligned} \tag{4}$$

The cubic electronic circuit had a transfer characteristic of $\text{f}_{\text{NL}}(x) = 0.01x^3$ as shown in Figure 1. Due to non-ideal characteristics there was a non-negligible quadratic term together with a linear term and a dc component in the fitted characteristic. Neither the quadratic term nor the dc offset enter into the theoretical calculations, but the linear component does, and it was taken into account in the comparisons between theory and the practical results described in Section III.

## III. Results and Analysis

Figure 4, 5 and 6 show the comparison of the BLA obtained through experiment results and those obtained from theory, for a Wiener system with (non-ideal, see (4)) cubic nonlinearity and RC filter linearity with $C = 1.5\text{nF}$ for all three cases and $R = 2.7\,\text{k}\Omega$, $27\,\text{k}\Omega$ and $110\,\text{k}\Omega$ respectively.

With $R = 2.7\,\text{k}\Omega$, the RC filter has a cut-off (or corner) frequency of $f_{\text{co}} = 1/2\pi RC \approx 39.3\,\text{kHz}$ and acts as an all-pass filter since the binary signal clock frequency was $f_{\text{c}} = 39\,{}^{1}\!/\!_{16}\,\text{kHz}$. Unfortunately this means ringing and overshoot effects (see Section II-D) were significant immediately after the RC filter stage. The linearity identification using m-sequences would yield unreliable results despite subsampling techniques. Here the use of non-parametric models of the linearity identified by a multisine was more suitable for the BLA theory. This can be seen by the fact that in Figure 4 the solid red line, representing the BLA theory based on a non-parametric linearity model identified with a multisine sequence, was able to match the experiment data represented by crosses more closely than that based on a linearity model (parametric or non-parametric) identified with a m-sequence. There are minimal differences between results derived from the non-parametric and parametric linearity models—the plots (cyan dashed and magenta heavy-dotted, respectively) are very close to each other.

For $R = 27\,\text{k}\Omega$, the RC filter had a corner frequency of approximately $3.93\,\text{kHz}$. Ringing and overshoot effects were then negligible immediately after the RC filter stage. Here the non-parametric models of the linearity for the m-sequence and multisine were used for their respective counterparts. In addition, the parametric model of (3) from Section II-E was used in the BLA theory to calculate the biased theoretical BLA for binary sequences. There were no discernible differences in the BLA theory calculated from the non-parametric and parametric linearity models as shown by the overlapping of the heavy-dotted magenta line and the solid red line in Figure 5.

When $R = 110\,\text{k}\Omega$, the RC filter had a corner frequency of about $0.965\,\text{kHz}$. The result is illustrated in Figure 6. This time parametric models up to order four produced by ELiS could not produce adequate quality fit to the transfer function of the linearity. Nevertheless the BLA theory based on the

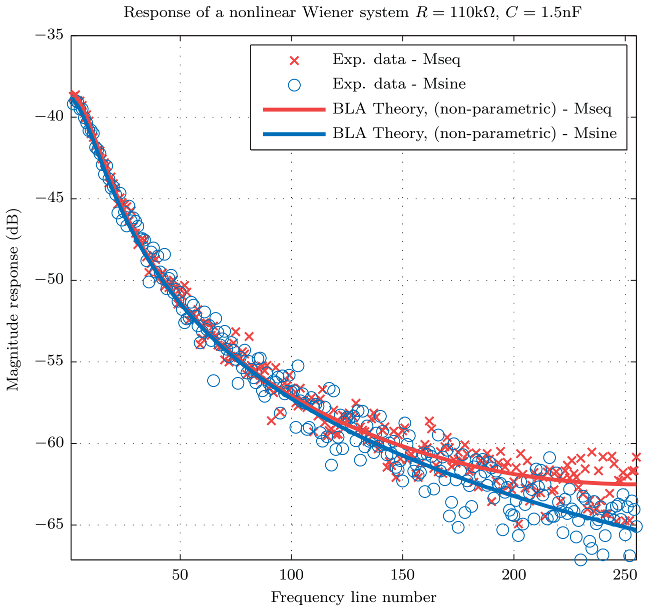

Figure 6. As Figure 4, but with $R = 110\text{k}\Omega$, giving corner frequency $f_{\text{co}} = 0.965\,\text{kHz}$.

non-parametric models was able to match the experiment data in both the gain and the shape of the transfer characteristics.

As the time constant of the system increases, the length of the impulse response of the system increases. It has been shown in Wong et al. [6] that this results in a BLA estimated by a signal with an arbitrary amplitude distribution converging to that obtained from Gaussian signal. This is also observed in Figures 4 to 6.

## IV. Conclusions

For all three sets of experiments investigated, it can be seen that the BLA theory prediction and experiment result are in good agreement. This is despite the fact that the BLA theory was based on impulse responses of the linearity modelled as finite-impulse-response (FIR) filters, whereas here the RC filter circuit is an infinite-impulse-response (IIR) filter.

The difficulties encountered with the experiment, mainly the ringing and overshoot effects illustrate a weakness in the z-domain discrete-time theory. It may therefore be beneficial to extend the theory to the continuous-time s-domain.

*Abstract*— A classical method of dealing with the non-linear elements in a transfer function is to assume that they can be separated from the linear section and can then be represented by describing functions. The standard method of calculating these describing functions has been to use a graphical method which breaks the non-linear characteristic into a series of linear sections and super-imposes their effects onto a sinusoidal input. The output is assumed to be a Fourier series and the Fourier transform for the first coefficient of this series is calculated in a piecemeal fashion. The process is not difficult but there is a considerable amount of calculation involved. In this paper an algorithm is presented which enables the describing functions of real non-linearities, with any number of linearized sections, to be simply written down without the usual onerous calculations. Additionally, a method of quickly sketching the general shape of describing functions is outlined.

***Keywords- non-linearity; describing function; limit-cycle.***

## I. INTRODUCTION

This paper begins by outlining the standard graphical method for obtaining describing functions and then proceeds to use the technique to develop a general solution for obtaining the family of real describing functions. These are the describing functions whose non-linear characteristics are the same irrespective of whether the magnitude of the input signal is increasing or decreasing. Obtaining a general solution also permits the creation of algorithms for its implementation and one such algorithm is presented. Although the general methods of deriving complex describing functions are well known, the real describing functions have usually been overlooked in the literature or else have been considered as trivial. This has meant that some simplifying approaches, and their associated algorithms, have been overlooked.

The purpose of developing a general method is to enable the easy and rapid delineation of the describing functions for real non-linearities – these are non-linearities which do not possess memory. To demonstrate the effectiveness of the general method, and the associated algorithm that has also been developed, the describing functions for two common linearities have been calculated: one which caused a single limit-cycle to be produced and one which caused two limit-cycles. The predicted limit-cycle results obtained by applying the algorithm were compared with simulations using SIMULINK.

## II. THE GRAPHICAL METHOD

The early development of the graphical describing function technique can be traced to several groups working independently [1], [2], [3], [4]. However these wartime developments did not come into general use until the mid - 1950s [4], [5], [8]. It is basically an harmonic balance approach modified for feedback control. This meant that only the principal harmonic was used and higher-order oscillations were considered to be negligible due to the filtering influence of the inertia inherent in the overall process which was being controlled. The basic graphical approach is shown in Figure 1. It is assumed that the input is sinusoidal (bottom left-hand corner of the diagram) and this is mapped via the non-linearity (represented at the top left-hand corner of the diagram) to an output. The input has an input magnitude *x* plotted against time *t*. The non-linear transformation translates this input magnitude *x*, on the horizontal axis, to the output magnitude *y* on the vertical axis. The output is a plot of output *y* against time *t*. This is the same time period as for the input signal and hence the output signal *y*, due to the non-linear transformation is correlated with the input.

Assuming a sinusoidal input, the input equation will be given by:

$$x = X.\sin(\omega t) \tag{1}$$

Since the non-linearity is symmetric about the origin, and since most systems behave like low-pass filters because of inertia, the output equation will be given by:

$$y = A_1 \sin(\omega t) \tag{2}$$

Hence the describing function is

$$N(X,\omega) = \frac{A_1}{X} \tag{3}$$

and there is only a need to calculate $A_1$.

Also, because of the quarter–wave symmetry:

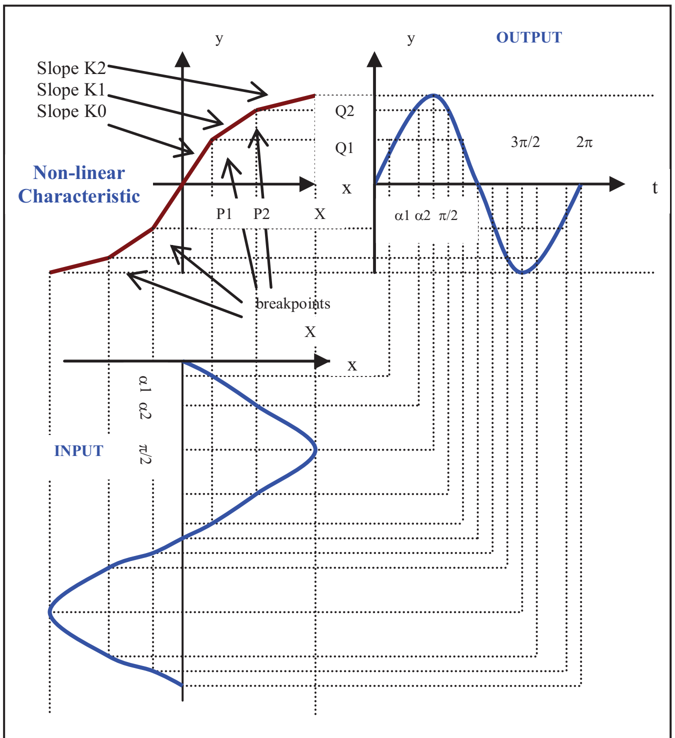

Fig. 1: The basic describing function graphical approach

$$A_1 = \frac{4}{\pi}\int_0^{\frac{\pi}{2}} y.\sin(\omega t).d(\omega t) \qquad (4)$$

The method is a quasi-linearization process in which a section of a static non-linearity is represented by a gain which depends on the magnitude of the input signal [6], [7], [9]. For this reason it is assumed that the non-linearity consists of lines of constant slope to each side of the break-points. The integrations can be calculated in a piecewise fashion to give:

$$A_1 = \frac{4}{\pi}\left[\int_0^{\alpha_1} y.\sin(\omega t).d(\omega t) \quad + \int_{\alpha_1}^{\alpha_2} y.\sin(\omega t).d(\omega t) \quad + \int_{\alpha_2}^{\frac{\pi}{2}} y.\sin(\omega t).d(\omega t)\right] \qquad (5)$$

where the individual values of $y$ in each of the separate linear sections have the form

$$y = Kx + c \qquad (6)$$

in which $K$ is the slope of the relevant section. The positions at which the slopes $K$ abruptly change value have been termed ***break-points*** in this investigation.

### *A. A General Solution*

Gibson and subsequent authors [7], [8], [9] showed how to obtain a general approach to the calculation of describing function by using this piecewise linear approach but aimed for an overall solution involving both real and imaginary parts. Also, although the early authors developed a general approach they only applied it case-by-case and did not present a general algorithm It is our opinion that a useful general algorithm can be obtained by considering single-valued non-linearities separately from double, or multi-valued, non-linearities and then specifically formulating a general solution. Single-valued non-linearities will produce real, as opposed to complex, describing functions and they can often be described by polynomial functions. By using this approach a general method for generating the describing functions of real non-linearities has been obtained. This work has resulted in a straightforward and relatively simple method of generating describing functions. An added advantage is that since there will be no phase-shifts, the superposition of the inverse Nyquist locus onto the describing function diagram is simplified since only one value of the inverse Nyquist locus, that at which it crosses the real axis, will need to be considered.

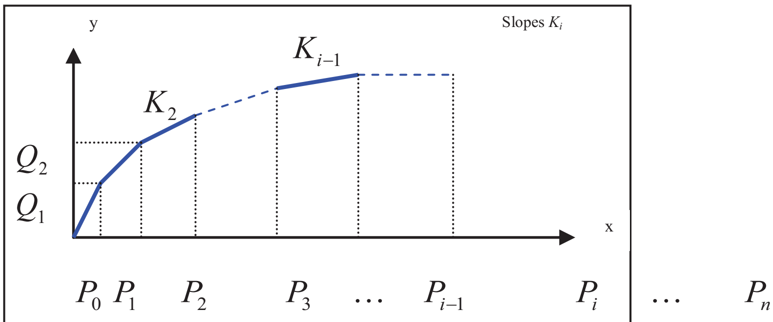

Fig. 2: Non-linear function with $n$ breakpoints

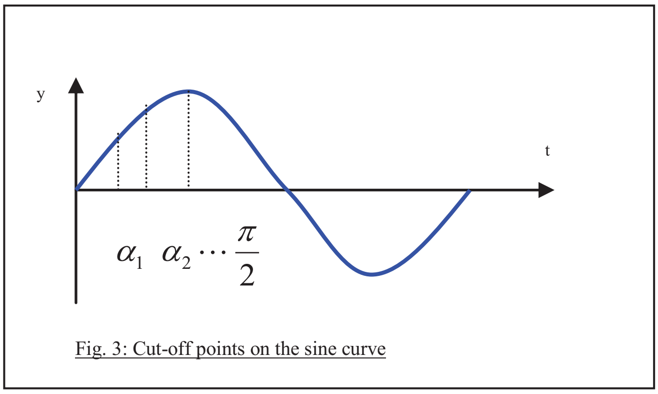

Fig. 3: Cut-off points on the sine curve

By taking Gibson's initial construction, in Fig. 1, with two breakpoints and extending it to $n$ breakpoints the graph will have $(n$ - 1) linear sections with slopes $K_0K_1 \ldots K_n$, and breakpoints occurring at horizontal positions $P_1P_2 \ldots P_n$ (with $P_0$ at the origin if necessary), jumps in the vertical plane (y-direction) at $Q_1Q_2 \ldots$ and angles on the sinusoidal input of $\alpha_1\alpha_2 \ldots \alpha_i \ldots \alpha_n, \frac{\pi}{2}$. The non-linearity will have the form shown in Fig. 2 (replacing the on-linear characteristic, top left-

GP would like to thank Prof. Ian Jenkinson, School of Engineering, Liverpool John Moores University for the facilities and support which enabled this work to be undertaken.

hand corner of Fig. 1 which maps the input signal to the output signal). The cut-off points on the sine curve will occur

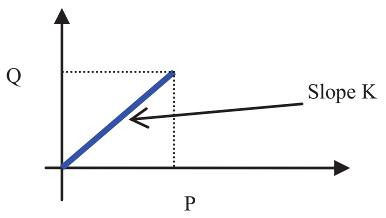

Fig. 4: Relationship between P and Q

as in Fig. 3 (replacing the sinusoidal-type of output in the top right-hand corner of Fig. 1.) The calculation of $A_1$ will be given:

$$A_1=\frac{4}{\pi}\left[\begin{array}{l}\int_0^{\alpha_1} y.\sin(\omega t).d(\omega t)+\int_{\alpha_1}^{\alpha_2} y.\sin(\omega t).d(\omega t)+\dots\\ \dots+\int_{\alpha_{i-1}}^{\alpha_i} y.\sin(\omega t).d(\omega t)+\dots+\int_{\alpha_n}^{\pi/2} y.\sin(\omega t).d(\omega t)\end{array}\right] \qquad (6)$$

which produces a general solution for the describing function:

$$N=\frac{2}{\pi}\left[K_n.\frac{\pi}{2}+\sum_{i=1}^{n}\left(K_{i-1}-K_i\right)\left(\sin^{-1}\left(\frac{P_i}{X}\right)+\left(\frac{P_i}{X}\right)\sqrt{\left[1-\left(\frac{P_i}{X}\right)^2\right]}\right)\right] \qquad \mathbf{(7)}$$

If Coulomb friction or relay action is present at initial amplitudes then equation (7) has to be adjusted.

Consider the case where only Coulomb friction is present: as $P\to 0\ \ y=Q$ , Fig. 4, $K_0=\infty\ \ and\ K_1=0$.

In this case, as $P\to 0,\ \sin^{-1}\left(\frac{P}{X}\right)\to\frac{P}{X}$ and

$$\left(\frac{P}{X}\right)\sqrt{\left[1-\left(\frac{P}{X}\right)^2\right]}\to\frac{P}{X}$$

Also from Figure (4), $P=\dfrac{Q}{K}$

Hence equation (7) reduces to $N=\dfrac{4Q}{\pi X}$ (8).

*B. An Algorithm*

An algorithm for using the general solution given in equation (7) and the special case of equation (8) to generate particular real describing functions is now presented. Although it specifically deals with discrete cases it can easily be extended to deal with continuous functions.

If Coulomb friction or relay action is present, start at stage one, otherwise start at stage two.

**Stage One:**

(a) If Coulomb friction or relay action is present then make $\dfrac{4Q}{\pi X}$ the first term of the describing function, where Q is the value of the Coulomb friction term.

(b) If dead-zone is also present multiply the above result by $\sqrt{\left[1-\left(\frac{P}{X}\right)^2\right]}$ where P is the dead-zone break-point.

**Stage Two:**

(a) If saturation is not present make $K_n$ the first term of the describing function. ($K_n$ is the gain of the last stage of the non-linearity) or add it to the result of stage one.

(b) If saturation is present then omit this term.

**Stage Three:**

(a) If there are $n$ breakpoints then add $n$ terms of the form

$$\frac{2}{\pi}(K_{i-1}-K_i)\left(\sin^{-1}\left(\frac{P_i}{X}\right)+\left(\frac{P_i}{X}\right)\sqrt{\left[1-\left(\frac{P_i}{X}\right)^2\right]}\right)$$

$$where\ i=0\to n.$$

Go to end.

(b) If saturation is present then change the last of the terms in stage 3(a) to

$$\frac{2}{\pi}K_{n-1}\left(\sin^{-1}\left(\frac{P_{n-1}}{X}\right)+\left(\frac{P_{n-1}}{X}\right)\sqrt{\left[1-\left(\frac{P_{n-1}}{X}\right)^2\right]}\right)$$

Go to end.

**End.**

## III. Derivation of Two Describing Functions Using the Algorithm

Two examples are presented (i) dead-zone plus saturation which can cause a single limit-cycle to be produced and (ii) a non-linearity which has three break-points (four pseudo-linear regions) and so can cause two nested limit-cycles to be produced. The effects of these non-linearities were then simulated by placing them in series with a transfer function for a third-order linear system and applying unity feedback. The simulations were created using the SIMULINK package.

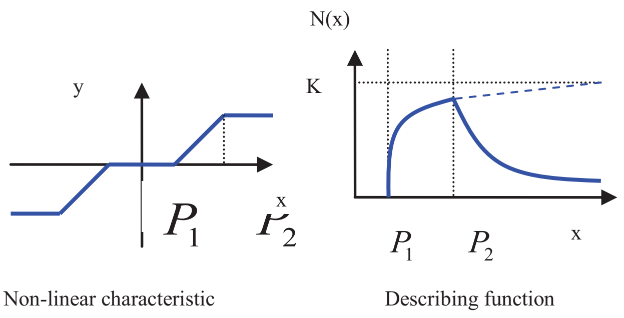

Fig. 5: dead-zone plus saturation

### A. *Dead-zone plus saturation*

The parameters are $n=2, K_0=0, K_1=K, K_2=0$ so equation (7) gives:

$$N=\frac{2K}{\pi}\left[\sin^{-1}\left(\frac{P_2}{X}\right)-\sin^{-1}\left(\frac{P_1}{X}\right)+\left(\frac{P_2}{X}\right)\sqrt{\left[1-\left(\frac{P_2}{X}\right)^2\right]}-\left(\frac{P_1}{X}\right)\sqrt{\left[1-\left(\frac{P_1}{X}\right)^2\right]}\right]$$

*when $X>P_2$; $N$ as for deadzone when $P_1<X\le P_2$ and $N=0$ when $X\le P_1$*

Using the algorithm, stages two (b), three (a) and three (b) apply and give the same result as above. This result is shown graphically in Fig. 5.

### B. *A non-linearity with three break-points (four slopes)*

In this case only one combination of slopes of the pseudo-linear sections has been considered: $K_0>K_1\ \&\ K_1<K_2\ \&\ K_2>K_3$.

In particular, $K_0=-0.7, K_1=0.2, K_2=1.5\ \&\ K_3=0.2.$ Again, the results were obtained by using equation (7), and by the algorithm, to give

$$N=\frac{2}{\pi}\left[\begin{array}{l}K_3.\frac{\pi}{2}+\left(K_2-K_3\right)\left[\sin^{-1}\left(\frac{P_3}{X}\right)+\left(\frac{P_3}{X}\right)\sqrt{\left[1-\left(\frac{P_3}{X}\right)^2\right]}\right]+\ldots\\ \left(K_1-K_2\right)\left[\sin^{-1}\left(\frac{P_2}{X}\right)+\left(\frac{P_2}{X}\right)\sqrt{\left[1-\left(\frac{P_2}{X}\right)^2\right]}\right]+\ldots\\ \left(K_0-K_1\right)\left[\sin^{-1}\left(\frac{P_1}{X}\right)+\left(\frac{P_1}{X}\right)\sqrt{\left[1-\left(\frac{P_1}{X}\right)^2\right]}\right]\end{array}\right]$$

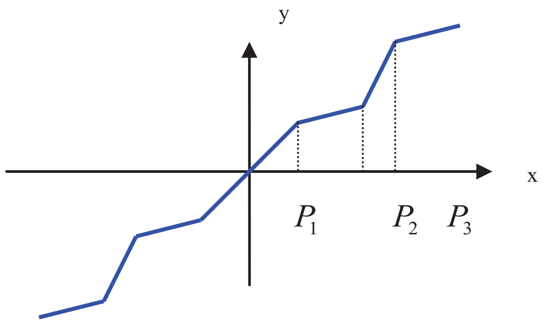

Fig.6(a): Non-linearity with three breakpoints

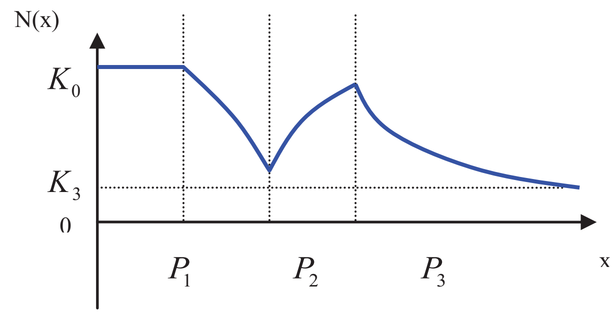

Fig. 6(b): Describing function for the three-breakpoint case

Using the algorithm, stages two (a) and three (a) apply. The graphical results are shown in Fig. 6(a) and Fig. 6(b).

## IV. USE OF REAL DESCRIBING FUNCTIONS TO PREDICT LIMIT-CYCLES

If the describing function is represented by N(X,ω) and the open-loop transfer function of a system is represented by G(jω) the Kochenburger's Stability Criterion [4] states that, in order for a system to remain stable, the locus $|G(j\omega)|$ must keep the entire locus ${-1}/{|N(X,\omega)|}$ on the right; or the inverse locus ${1}/{|G(j\omega)|}$ must keep the locus $-|N(X,\omega)|$ on the left (or must completely enclose the whole of the locus). For this work the authors found that the inverse Nyquist approach was more convenient. Furthermore, since only systems with real, as opposed to complex, describing functions were being investigated, plots with real and imaginary axes were of little use. It was better to plot the magnitude of the describing functions against the magnitude of the input signal and to superimpose on this the magnitude of the inverse Nyquist value at which it crossed the real axis. The position at which the descending describing function locus crossed the inverse Nyquist value then enabled the magnitude of the limit-cycle to be determined – as shown in Fig. 7.

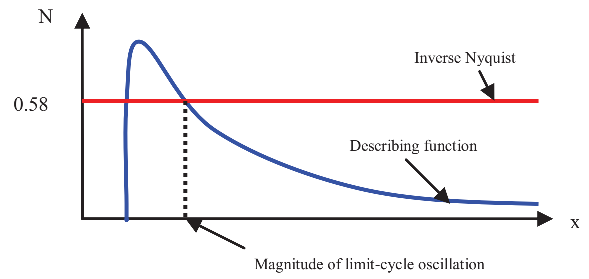

Fig. 7: A real describing function locus with an inverse Nyquist magnitude superimposed on it.

A similar approach was tried [10] using the direct Nyquist instead of the inverse function but it didn't lend itself to the same predictive opportunities.

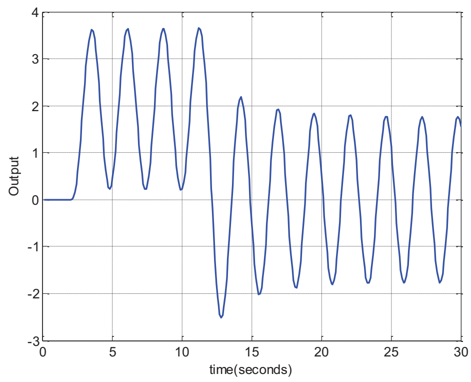

Fig. 8: Limit-cycle oscillation with saturation and dead-zone

### A. Dead-zone plus saturation

According to the basic describing function locus shown in Fig. 5 this has the potential to exhibit the limit-cycle effect. The system was simulated in series with a third-order transfer function and the oscillatory response shown in Fig. 8 was obtained. This oscillatory response was produced with the limits of the saturation non-linearity set to ±1 and dead-zone set to ±0.5.

The calculated magnitude of the limit-cycle, from Fig. 10, is 1.79 ± 0.02. The actual magnitude of the limit-cycle, from Fig. 9, is 1.78 ± 0.03. The calculated frequency of oscillation is 2.45±0.001 rad/s and, from Figure 9 the measured frequency of oscillation is 2.44 ± 0.03 rad/s

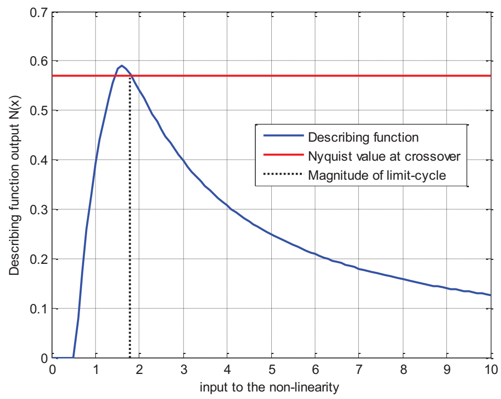

Fig. 9: Plot of describing function of dead-zone plus saturation

### B. The non-linearity with three break-points (four slopes)

This time there were two positions where limit-cycles might occur depending on the signal input magnitude.

From Fig. 10, the measured frequency of the limit-cycle oscillation was 2.41 ± 0.07 rad/s which compared with the calculated limit-cycle frequency of 2.45 ± 0.001 rad/s. From Figure 11 the calculated magnitude of the lower limit-cycle was 1.60 ± 0.05 and of the higher limit-cycle it was 9.2 ± 0.08. From Fig. 10 the actual magnitude of the lower limit-cycle was 1.52 ± 0.7 and of the higher limit-cycle it was 10.1 ± 1.2.

It was found, by successively increasing the values of the second impulse magnitude, that the second limit-cycle was reached once the impulse had been raised above about 5.6, although it took several oscillation to reach this new stable position. Again, this could be predicted from Figure 11 where the rising value of the describing function crossed the Inverse Nyquist.

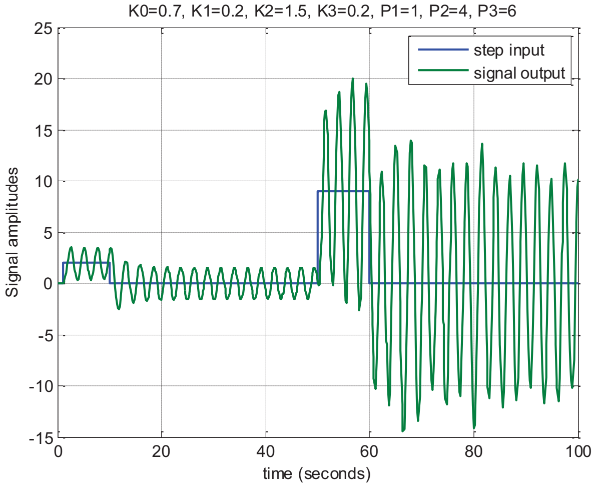

Fig. 10: The three-breakpoint response showing two limit-cycles

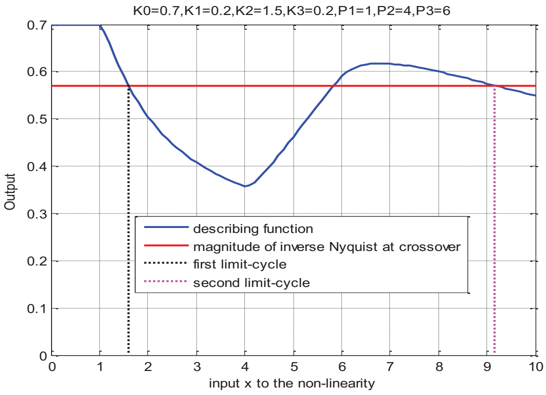

Fig.11: Describing function for the three break-point characteristic

## V. A QUICK METHOD OF SKETCHING DESCRIBING FUNCTIONS

In every case investigated, both in those shown in Figures 5 and 6(b) and in more complicated real non-linearities, the slope of the 'linear' section became the asymptotic value to which that section of the describing function tended. Also, there was an abrupt change in the describing function at the same value of x as that at which the break-value of the non-linearity occurred. When $|K_n| > |K_{n-1}|$ the locus increased in value approximately to the formula: $y = K_{n-1} + (K_n - K_{n-1})(1 - e^{-x})$ and when $|K_n| < |K_{n-1}|$ the locus decreased in value approximately to the formula: $y = K_n + (K_{n-1} - K_n)e^{-x}$. A more precise mathematical description of each type of locus was not considered necessary since the observed behaviour has only been used in subsequent work to afford a rough sketch of the shape of the describing function. A sketch can be performed more rapidly than using the algorithm to give a general outline of the shape before the algorithm itself is used to give more precise results.

## VI. CONCLUDING REMARKS

This work has used the classical method for deriving describing functions. However, by restricting the formulation to deal only with those non-linearities which produce real, not complex, describing functions it has been possible to devise an algorithm which enabled such functions to be simply written down without the usual onerous calculations. Furthermore, the method could be rapidly applied to non-linearities of considerable complexity. Also, because only real describing functions were being considered, it was possible to use a simplified graphical form of Kochenburger's criteria to derive the positions of limit-cycles and also the range of inputs needed to induce them. After the derivation of the algorithm two examples of non-linearities have been presented, one which produces a single limit-cycle and one which produces two nested limit-cycles. The expected parameters which produced these effects have been calculated and compared with the actual results obtained by simulation. Finally a quick method of producing a rough sketch of the general shape of a describing function has been included. This paper presents the first stages of a series of investigations into non-linear effects and their control.

***Abstract*—Pulmonary characteristics differ in patients, and the suitable setting of ventilation condition is needed for every patient in the artificial respiration. The pulmonary elastance is one of the important features of lung, and it is a basis for deciding the airway pressure limit value. To get the pulmonary elastance of the of the patient from measurement data of the artificial respiration, the fuzzy logic technique has been proposed for estimating the pulmonary elastance and the static $P-V$ curve in our previous works. In this paper, a new technique of fuzzy modeling based on data combination of two respiration phases is proposed to improve the estimation precision, and some estimation examples using real patient data are given to illustrate the superiority of the proposed method over the previous algorithm in the precision.**

*Key Words*—**modeling, estimation, fuzzy logic, artificial respiration, elastance**

## I. INTRODUCTION

Artificial respirator is used for patients with little or no autonomous breathing ability. Using a respirator, particular attention should be paid to set suitable ventilation condition. Pulmonary characteristics differ in patients and change by the extent of illness progress or recovery. Now, the setting of the respirator is decided by the experience and the intuition of the doctor. This is a problem that there is no appropriate method for deciding ventilation condition. This problem may cause a medical accident. These circumstances motivate us to develop a method to estimate the pulmonary elastance of the patient and to set a ventilation condition of the artificial respirator.

In our previous work, we have presented an estimation technique of the pulmonary elastance by fuzzy logic, and have represented the static $P-V$ curve needed for the respirator setting. However, the estimation precision of previous technique was not satisfactory, the estimated static $P-V$ curve cannot be used for the respirator setting. In this paper, we improved the estimation precision by new technique that combine the measurement data of two phases of breath. Furthermore, this paper shows some estimation examples using real patient data to illustrate the superiority of the proposed method over the previous algorithm in the precision.

The paper is organized as follows. Section 2 introduces the static $P-V$ curve and nonlinear differential equation model of respiratory systems. A new method that estimating the pulmonary elastance by fuzzy logic is described in Section 3. Some examples of estimation are given in Section 4. Finally, Section 5 concludes this paper.

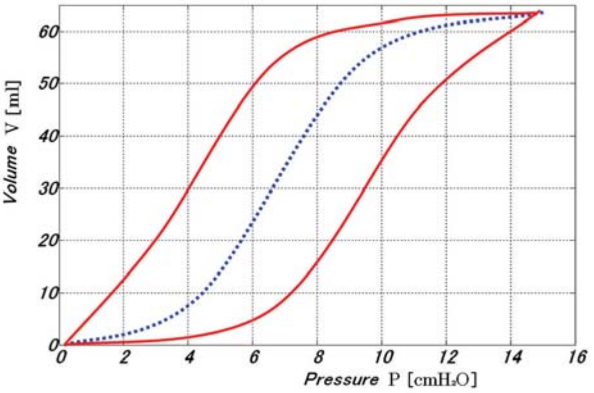

Fig.1. The dynamical $P-V$ curve (solid line) and the static $P-V$ curve (dotted line).

## II. NONLINEAR DIFFERENTIAL EQUATION MODEL OF RESPIRATORY SYSTEMS

The static state is a state without the flow of air in the respiratory system. In this state, the static $P-V$ curve is drawn by the pressure ($P_l(t)$) and the volume ($V(t)$) inside of lung. The gradient of the static $P-V$ curve is the compliance, and the inverse of the compliance is the elastance of the lung. The pulmonary elastance ($f_E(V)$) is as a nonlinear function of $V(t)$, and the static $P-V$ curve is expressed by the following equation:

$$P_l(t) = f_E(V)V(t). \qquad (1)$$

978-1-4673-1560-9/12/$31.00 ©2012 IEEE

This static $P-V$ curve expresses the important feature of the lung, and it is a basis for deciding the air-way pressure limit value.

Fig.1 shows the dynamic $P-V$ curve (solid line) and the static $P-V$ curve (dotted line) by respiratory data over one period. The dynamic $P-V$ curve can be drawn by air-way pressure and air-volume of lung that can be measured directly. However, the static $P-V$ curve cannot be drawn directly, because inside pressure of lung cannot be measured directly. So, we must estimate the static $P-V$ curve by technique of the system identification.

For a rational setting of the respirator, a mathematical model is needed to describe the respiration. Some related works are addressed in the literature[2][3]. The lung of human is divided into right and left. Even if each lung is modeled by a simple first order differential equation, the synthesized overall respiratory system model becomes to second order differential equation [1]. Respiratory system model as the following equation is proposed by Kanae *et al*,

$$\begin{aligned} P_{ao}(t) + a_1\dot{P}_{ao}(t) &= f_E(V)V(t) \\ &+ g_R(\dot{V})\dot{V}(t) + b_2\ddot{V}(t) + P_{eea} + \epsilon(t), \end{aligned} \tag{2}$$

where $P_{ao}(t)$ is air-way opening pressure, $F(t) = \dot{V}(t)$ is air-flow, $P_{eea}$ is the end-expiratory alveolar pressure. In addition, $g_R(\dot{V})$ is so-called air-way resistance. The pressure loss $P_r$ is expressed by the following equation,

$$P_r(t) = g_R(F)F(t) = (r_1 + r_2|\dot{V}(t)|)\dot{V}(t). \tag{3}$$

The pulmonary elastance and the air-way resistance are described by polynomials of volume $V(t)$. $\epsilon(t)$ contains the modeling error and the measurement noise. In the model (2), the order of equation are the same as the conventional model[2]. Therefore, the model has the capability of describing the nonlinear dynamical characteristics of respiration. We can measure air-way opening pressure, volume, air-flow in each sampling period.

The fuzzy logic is suitable for expressing a nonlinear function, and can reduce computational complexity in the estimation by the fuzzy division. After that, using this respiratory system model (2), this study presents a method to estimate the pulmonary elastance by fuzzy logic.

## III. FUZZY MODEL OF RESPIRATORY SYSTEMS

### A. Fuzzy Logic

Mamdani's fuzzy IF-THEN rules are very famous in fuzzy logic[4]. The structure of these rules is that all inputs are set in part of the antecedent and all outputs are set in part of the consequent.

In this study, the volume $(V(t))$ is defined as the part of the antecedent and pulmonary elastance of the first order function of $(f_E(V) = k_1+k_2V)$ is defined as the part of the consequent. Fuzzy variables in part of the antecedent are defined as $small$, $medium$, $big$.

### B. Previous Method

Using technique called Functional Type SIRMs (Single Input Rule Modules) fuzzy reasoning method, We estimated the pulmonary elastance in previous study. Functional Type SIRMs fuzzy reasoning method is proposed by Seki *et al* [5]. Firstly, this method defines IF-THEN fuzzy rule modules of single input type. The overall reasoning result is weighted sum of the reasoning results of each rule modules. In this study, input term $V$ is divided into the inspiratory volume $V_{in}$ and the expiratory volume $V_{out}$. Therefore, fuzzy rules is structured as follows,

$$\begin{aligned} & Rule - V_{out}: \\ & if \;\; V_{out} = small_{out}, \\ & \;\; then \;\; f_{Eout(small)} = k_{1out(small)} + k_{2out(small)}V; \\ & if \;\; V_{out} = medium_{out}, \\ & \;\; then \;\; f_{Eout(medium)} = k_{1out(medium)} + k_{2out(medium)}V; \\ & if \;\; V_{out} = big_{out}, \\ & \;\; then \;\; f_{Eout(big)} = k_{1out(big)} + k_{2out(big)}V. \\ & \\ & Rule - V_{in}: \\ & if \;\; V_{in} = small_{in}, \\ & \;\; then \;\; f_{Ein(small)} = k_{1in(small)} + k_{2in(small)}V; \\ & if \;\; V_{in} = medium_{in}, \\ & \;\; then \;\; f_{Ein(medium)} = k_{1in(medium)} + k_{2in(medium)}V; \\ & if \;\; V_{in} = big_{in}, \\ & \;\; then \;\; f_{Ein(big)} = k_{1in(big)} + k_{2in(big)}V. \end{aligned} \tag{4}$$

The consequent part parameters of fuzzy rules (4) are estimated by the numerical integration technique and the least squares method[1][6]. The reasoning result of each rule modules is calculated by the Center of Gravity Method as follows,

$$\begin{aligned} & Rule - V_{out}: \\ & h_j^{V_{out}} = A_j^{V_{out}}(V^0), \qquad (j = small, medium, big), \\ & f_{Eout}^0 = \frac{\sum_{j=small}^{big} h_j^{V_{out}} f_{Eout(j)}(V^0)}{\sum_{j=small}^{big} h_j^{V_{out}}}; \end{aligned} \tag{5}$$

$$
\begin{aligned}
&Rule - V_{in}: \\
&h_j^{V_{in}} = A_j^{V_{in}}(V^0), \qquad (j = small, medium, big), \\
&f_{Ein}^0 = \frac{\displaystyle\sum_{j=small}^{big} h_j^{V_{in}} f_{Ein(j)}(V^0)}{\displaystyle\sum_{j=small}^{big} h_j^{Vin}},
\end{aligned}
\tag{6}
$$

where, $A$ is fuzzy set of the antecedent variable $V$, $h_j$ is the conformity degree of the antecedent.

The overall reasoning result $f_E^0$ can be calculated as follows:

$$
f_E^0 \;=\; \omega_{Vout}\, f_{Eout}^0 \;+\; \omega_{Vin}\, f_{Ein}^0, \tag{7}
$$

where, $\omega_i$ ( $i = Vin, Vout$ ) is so-called the serious consideration degree for the overall reasoning result.

Finally, $f_E^0$ is substituted for relation equation between the pressure ($P_l$) and the volume ($V$) inside of lung as follows:

$$
P_l \;=\; f_E^0\, V. \tag{8}
$$

The static $P - V$ curve is drawn by equation (8).

However, estimation precision for this technique was not satisfactory. We will explain a process to improve estimation precision later.

### C. Estimation of consequent part parameters of the fuzzy rule

This section introduces the method that estimates the function parameters of consequent part about an arbitrary rule in fuzzy rule of equation (4). Using the respiratory system model, the first order function ($f_E(V) = k_1 + k_2 V$) substitutes the relationship of

$$
\begin{aligned}
P_{ao}(t) + a_1\dot{P}_{ao}(t) &= k_1 V(t) + k_2 V^2(t) \\
&\quad + g_R(\dot{V})\dot{V}(t) + b_2\ddot{V}(t) + P_{eea} + \epsilon(t)\ .
\end{aligned}
\tag{9}
$$

Define data vector $\varphi(t)$ and parameter vector $\theta$ as follows: $\varphi^T(t) = [-\dot{P}_{ao}(t),\ V(t),\ V^2(t),\ \dot{V}(t),\ |\dot{V}(t)|\dot{V}(t),\ \ddot{V}(t),\ 1.0]$; $\theta^T = [a_1, k_1, k_2, r_1, r_2, b_2, P_{eea}]$. Then, using relationship between the volume and the flow ($F(t) = \dot{V}(t)$), data vector $\varphi(t)$ can be written as follows: $\varphi^T(t) = [-\dot{P}_{ao}(t),\ V(t),\ V^2(t),\ F(t),\ |F(t)|F(t),\ \dot{F}(t),\ 1.0]$ .

The model equation can also be written in short form as follows:

$$
P_{ao}(t) \;=\; \varphi^T(t)\theta + \epsilon(t)\ . \tag{10}
$$

Equation (9) is continuous-time model. An identification model is obtained by applying the numerical integration technique which is known as an effective approach for continuous-time model identification[7].

Measurement data are sampled data of air pressure $P_{ao}(k)$, flow $F(k)$, volume $V(k)$, where $k$ ( $k = 1, 2, \cdots, N$ ) denotes sampling instant. $N$ define the data size. $T$ define the sampling period of data collection. Then, at time instant $t = kT$, integrate both sides of equation (10) over the interval $[(k-\ell)T, kT]$. Using the numerical integration technique that is proposed by Sagara *et al*, left side of equation (10) can be calculated as follows:

$$
y(k) \;=\; \int_{(k-\ell)T}^{KT} P_{ao}(\tau)d\tau \;\doteq\; \sum_{j=0}^{\ell} g_j P_{ao}(k-j), \tag{11}
$$

where, $\ell$ is a natural number that decides the window size of numerical integration. The coefficients $g_i (i = 1, 2, \cdots, \ell)$ are determined by formulae of numerical integration. When the trapezoidal rule is taken, they are given as follows:

$$
\begin{cases}
g_0 = g_\ell = T/2, \\
g_i = T, \quad i = 1, 2, \cdots, \ell - 1.
\end{cases}
\tag{12}
$$

As calculation of equation (11), data vector $\varphi(t)$ can be calculated by

$$
\begin{aligned}
\phi(k) \;&=\; \int_{(k-\ell)T}^{KT} \varphi(\tau)d\tau \\
&= \begin{bmatrix}
-P_{ao}(k) + P_{ao}(k-\ell) \\
\displaystyle\sum_{j=0}^{\ell} g_j V(k-j) \\
\displaystyle\sum_{j=0}^{\ell} g_j V^2(k-j) \\
V(k) - V(k-\ell) \\
\displaystyle\sum_{j=0}^{\ell} g_j |F(k-j)| F(k-j) \\
F(k) - F(k-\ell) \\
\ell T
\end{bmatrix}.
\end{aligned}
\tag{13}
$$

Get together the approximation error $\Delta_E$ caused by numerical integration and the integral of original error term $\epsilon$ in $e(k)$. Namely, Let $e(k)$ be

$$
e(k) \;=\; \Delta_E \;+\; \int_{(k-\ell)T}^{KT} \epsilon(\tau)d\tau. \tag{14}
$$

Consequently, an identification model of discrete-time form is provided from equation (11), equation (13) and equation (14) as follows:

$$
y(k) \;=\; \phi^T(k)\theta \;+\; e(k)\ . \tag{15}
$$

From the measurements of air pressure $P_{ao}(k)$, flow $F(k)$, volume $V(k)$, calculates $y(k)$ and $\phi(k)$ at each time instant $k = \ell + 1, \cdots, N$. And the vector equation is structured by them as follows:

$$
\mathbf{y} = \mathbf{\Phi}\theta + \mathbf{e}, \tag{16}
$$

where, $\mathbf{y} = [y(N)\cdots y(\ell+1)]^T$, $\mathbf{\Phi} = [\phi(N)\cdots\phi(\ell+1)]^T$, $\mathbf{e} = [e(N)\cdots e(\ell+1)]^T$.

The least squares estimate that minimizes the criterion function $J = \| \mathbf{y} - \mathbf{\Phi}\theta \|^2$ is given by

$$\hat{\theta} = (\mathbf{\Phi^T \Phi})^{-1}\mathbf{\Phi^T y}. \tag{17}$$

Then, the function of consequent part about an arbitrary rule in fuzzy rules (4), in other words, the function of pulmonary elastance is estimated as

$$\hat{f}_E(V) \ = \ \hat{k}_1 + \hat{k}_2 V \ . \tag{18}$$

Executing the above-mentioned calculation on all fuzzy rules, fuzzy rules are made.

### D. New Method

It is considered that there are two reasons to result unsatisfactory precision of estimation. One is that the design of serious consideration degree has to be performed by hand-operation. Another one is that there is relatively large error in each connection area of two fuzzy rules, and the whole precision becomes worse as the partition number of variable increased. We are going to solve these two problems here.

The idea is to combine the data of two respiratory phases. Firstly, prepares the regression data in each range of fuzzy variables according to equation (16). Then, combines the data of two phases of expiratory and inspiratory respiration in every same range. Consequently, the fuzzy rules are combined as follows:

$$\begin{aligned}
&if\ V = small,\\
&\quad then\ f_{E(small)} = k_{1(small)} + k_{2(small)}V;\\
&if\ V = medium,\\
&\quad then\ f_{E(medium)} = k_{1(medium)} + k_{2(medium)}V;\\
&if\ V = big,\\
&\quad then\ f_{E(big)} = k_{1(big)} + k_{2(big)}V.
\end{aligned} \tag{19}$$

Using combined data, the parameters of the consequent part of the fuzzy rules (19) are estimated by the least squares method as mentioned above.

Using above fuzzy rules (19), the overall reasoning result of pulmonary elastanse is estimated. The reasoning result of fuzzy rules (19) is calculated by the Center of Gravity Method as follows:

$$\begin{aligned}
h_j^V &= A_j^V(V^0), \qquad (j = small, medium, big),\\
f_E^0 &= \frac{\sum_{j=small}^{big} h_j^V f_{E(j)}(V^0)}{\sum_{j=small}^{big} h_j^V}.
\end{aligned} \tag{20}$$

where, $A$ is fuzzy set of the antecedent variable $V$, $h_j$ is the conformity degree of the antecedent. The static $P-V$ curve is drawn by equation (8).

In this way, problems of a calculation error and the serious consideration degree are solved by combining the data of two phases of breath.

## IV. EXAMPLES OF ESTIMATION

In this section, some experimental results are shown to estimate the static $P-V$ curve with real clinical data of artificial respiration. Here, ranges of the fuzzy variables ($small$, $medium$ and $big$) are set by manual operation and each of the serious consideration degree is assumed as degree of 0.5. Fig.2 and Fig.4 are membership functions of the fuzzy variables in each experiment. Fig.3 and Fig.5 are experimental results that estimate static $P-V$ curve with real clinical data of artificial respiration. The circle points and the square points are quasi-static elastance $P-V$ points for inspection. It is shown that the estimated static $P-V$ curve passes near of inspection data similar the true static $P-V$ curve. Table.1 is mean-square error of estimated static $P-V$ curve by each method to inspection data. Table.1 shows that estimated static $P-V$ curve by new method passes near of inspectional data points.

It is important that we must set suitable range of the fuzzy variables. In these experiments, we were able to find suitable values by a hand-operated design. However, the estimated precision is not satisfactory when fuzzy variables are not suitable values. Considering of the problems mentioned above and pulmonary characteristics that differ in patients, it is necessary to devise optimization algorithm for range setting of the fuzzy variables. Finally, we aim at the automation of estimation of pulmonary elastance and the improvement of estimated precision in the future.

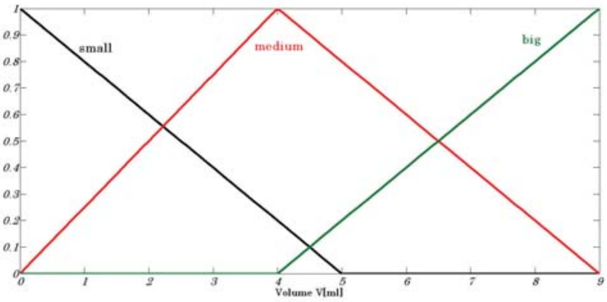

Fig.2. Data1: Membership functions of fuzzy variables.

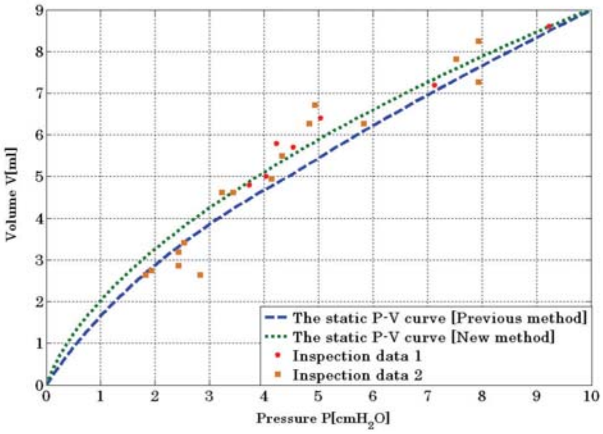

Fig.3. Data1: Estimated static $P - V$ curve and experimental static elastic recoil pressure-volume points(◯, □).

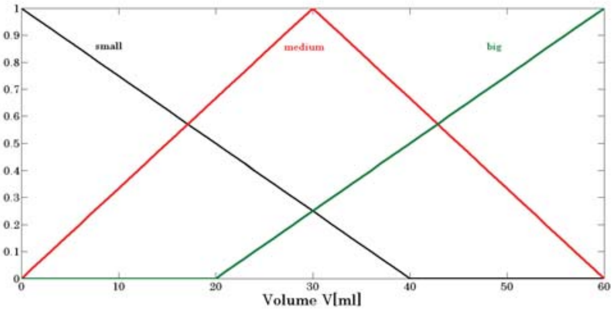

Fig.4. Data2: Membership functions of fuzzy variables.

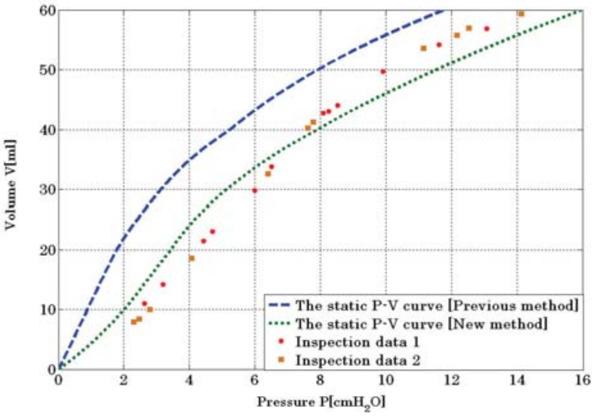

Fig.5. Data2: Estimated static $P - V$ curve and experimental static elastic recoil pressure-volume points(◯, □).

## V. CONCLUSIONS

The pulmonary elastance is one of the important features of lung, and it is a basis for deciding the air-way pressure limit value. In this study, an estimation method of pulmonary elastance based on fuzzy logic is proposed. Using technique to combine the data of two phase of breath, one fuzzy rule that merged the expiratory fuzzy rule with the inspiratory fuzzy rule is made. The reasoning result of fuzzy rule is calculated by the Center of Gravity Method.

TABLE I
MEAN-SQUARE ERROR OF ESTIMATED STATIC $P - V$ CURVE BY EACH METHOD TO INSPECTION DATA.

| | Previous [cmH$_2$O] | New [cmH$_2$O] |
|---|---|---|
| Data 1 | 0.5658 | 0.3525 |
| Data 2 | 5.4845 | 1.2985 |

As a result of estimated pulmonary elastance with real clinical data of artificial respiration, we can draw the static $P-V$ curve that passes near of inspectional data points. However, it is necessary to set suitable range of the fuzzy variables of the antecedent part. Therefore, by devising optimization algorithm for range setting, we aim at the automation of estimation of pulmonary elastance and the improvement of estimated precision in the future.

*Abstract*—**This work is based on adapting suitable techniques in real-time aircraft system identification for the use in rigid body dynamic modelling of Unmanned Aerial Vehicles (UAVs). In general due to their reduced size UAVs lend themselves well to the recovery of flight data in full scale atmospheric trials. Timely recovery of the true model parameters is necessary to minimise flight tests for rapid prototype development. Using the Cranfield University Jetstream-31 Flying Laboratory (G-NFLA) as a test bed an investigation into suitable parameter update methods applicable for UAV purposes is being performed; and builds on previous work which considered the constraints pertinent to small UAVs, such as the absence of air flow vanes.This paper outlines an approach to achieve post-manoeuvre parameter estimation by applying the equation-error method in the frequency domain, and an example using flight data for the Jestream-31 flying laboratory is presented.**

## I. Introduction

### A. Background

With the evolution of aircraft design and manufacture, flight testing still remains an integral aspect of the process; however, commercial demands require that a flight campaign achieve its goals in the minimal time possible. Advances in simulation and wind-tunnel modelling enable us to better predict aircraft dynamics which are necessary for the development of flight control laws, and provide the starting point for full-scale trials. Numerous examples of aircraft system identification (SysID) to determine suitable dynamic models for manned aircraft are widely reported [1], [2]. Despite the rapid development of UAV platforms widespread application of this technique has yet to occur in the unmanned field.

Real-time SysID was primarily driven by the need to monitor highly unstable aircraft behaviour in non-linear flight regimes, while expanding the operational flight envelope [3]. Recent development has focused on creating self-healing control systems, such as adaptive re-configurable control laws to provide robustness against airframe damage or control surface failures [4], [5]. In the case of UAVs real-time identification, would facilitate rapid prototyping especially in low-cost projects with their constrained development time. Development of SysID for a small UAV scenario could lead to flight trials focused towards dynamic model validation, with the prior verification step done using the simulation environment.

Therefore, current research in the department is primarily concerned with developing post-manoeuver estimation of the aerodynamic derivatives, and builds on the work undertaken by Carnduff [6] which outlined SysID methods for UAVs. The ability to check the estimated derivatives while the aircraft is flying would enable detection of poor data readings due to deficient excitation manoeuvres or atmospheric turbulence. Subsequently, appropriate action could then be taken while all the equipment and personnel are in place.

### B. Aircraft system identification

A brief explanation of key points relating to the process of aircraft SysID will now follow, an in-depth explanation can be found in [7]. The conventional SysID method can be seen in figure 1, the process depends on the *a priori* knowledge about the aircraft and is then followed by five distinct steps: experiment design, Data Compatibility Check (DCC), model structure determination, parameter estimation and model validation.

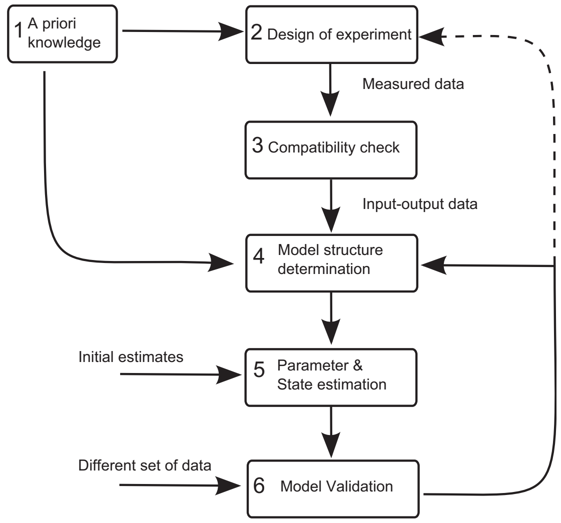

Fig. 1. An overview of the SysID process, [8].

The experiment design relates to the type of input used to perturb the aircraft from an initial state of balanced forces

Fig. 2. The Cranfield Jetstream-31 flying laboratory

and moments defined as *trim*, chosen to be a steady level flight condition for this study. The DCC step processes the data for kinematic consistency between the inertial and air data, thus allowing sensor errors or data drop-outs to be dealt with. In certain cases the model structure for the aircraft is then determined from the data, the model is then populated with the estimated model parameters and states. Finally, the representative model is validated by using a separate data set not previously used during the modelling process. Should a validation fail, alternative model structures or estimation techniques should be trialled before making the expensive decison to use a different excitation input (dotted line in figure 1). From *a priori* knowledge of the aircraft: the data was known to be compatible therefore the DCC step was neglected, and reduced order models were postulated enabeling the SysID process to proceeded directly to the Parameter Estimation (PE) step.

### C. Jetstream Aircraft

G-NFLA shown in figure 2 operates as the United Kingdom's National Flying Laboratory Aircraft and is primarily used to demonstrate flight dynamics principles to undergraduate students. As a result the types of excitation inputs used are limited to impulses and doublets. The aircraft is instrumented with an Inertial Reference System (IRS), GPS, and air data probes. Displays in-front of every seat (similar to an in-flight entertainment display) are driven by an on-board computer which transforms the measured data into strip-charts and guages depending on the topic being covered. It is anticipated that this computer will be used to run the parameter estimation algorithms; therefore an emphasis has been placed on incurring minimal additional computational burden. Current practice is to retrieve the recorded flight data from the computer hard drive for post-flight analysis using a USB key.

### D. Motivation

The aim of the current work is to develop a flexible tool box for post-manoeuver parameter estimation for UAVs. Using G-NFLA as a flying test-bed, suitable algorithms have been tested with postulated models for the reduced order SPPO, and Dutch Roll modes. As flight test data is primarily available on an opportunistic basis, the ability to reduce processing time would maximise such opportunities.

## II. Method

### A. Models

From the *a priori* knowledge about the aircraft, the standard rigid body equations of motion can be used to formulate a model which accurately describes the aircraft dynamics. The assumption when using such models is that the longitudinal and lateral dynamics are suitably distinct in order to be decoupled. The following body axes models are taken from [9], where the SPPO model is:

$$\begin{bmatrix} \dot{\boldsymbol{W}} \\ \dot{\boldsymbol{q}} \end{bmatrix} = \begin{bmatrix} Z_w & Z_q \\ M_w & M_q \end{bmatrix} \begin{bmatrix} \boldsymbol{W} \\ \boldsymbol{q} \end{bmatrix} + \begin{bmatrix} Z_\eta \\ M_\eta \end{bmatrix} [\boldsymbol{\eta}] \tag{1}$$

and the Dutch Roll model is:

$$\begin{bmatrix} \dot{\boldsymbol{V}} \\ \dot{\boldsymbol{r}} \end{bmatrix} = \begin{bmatrix} Y_v & Y_r \\ N_v & N_r \end{bmatrix} \begin{bmatrix} \boldsymbol{V} \\ \boldsymbol{r} \end{bmatrix} + \begin{bmatrix} Y_\zeta \\ N_\zeta \end{bmatrix} [\boldsymbol{\zeta}] \tag{2}$$

Here it must be noted that the above stability and control derivatives are in concise form, and therefore require manipulation in order to relate them to the respective non-dimensional values (see appendix of [9]).

### B. Body Translational Rates

Typically, large aircraft can be readily equipped to measure air data using $\alpha$- or $\beta$-vanes; these measurements enable the body translational rates: $u_b$, $v_b$ and $w_b$ to be determined and form part of the dependent variables shown in equations 1 and 2. In smaller UAVs access to such air data measurements can prove unfeasible. In the absence of these vanes, measurements from an IRS can be used to calculate the translational rates (see [10], [11]). These rates can be determined using 'track-fixed' accelerations; neglecting turbulence the IRS has more reliable sensors with respect to the analog vane type instruments.

### C. Frequency Domain Transformation

With reference to Klein [12] and more recently Morelli [13] the Equation-Error method in the frequency domain can be formulated. Analysis in the frequency domain using the finite Fourier Transform method is better suited to the linear model identification being considered for two key points. Firstly, when the Fourier transform is applied the bias and drift in the measured data is removed. Secondly, using *a priori* knowledge of the expected frequency range the data to be analysed can be easily reduced. Further to the above benefits, differentiation and convolution in the frequency domain simplifies to multiplication by $j\omega$, allowing terms such as $\dot{p}$, $\dot{q}$, $\dot{r}$ and $\dot{u}_b$, $\dot{v}_b$, $\dot{w}_b$ to be calculated. Considering the aircraft model in state space form:

$$\dot{x}(t) = \mathbf{A}x(t) + \mathbf{B}u(t), \quad x(0) = 0 \tag{3}$$

$$y(t) = \mathbf{C}x(t) + \mathbf{D}u(t) \tag{4}$$

$$z(t) = y(t) + \nu(t) \tag{5}$$

where *x(t)*, *u(t)*, and *y(t)* are the state, input and output vectors, *z(t)* is the measurement equation with error $\nu(t)$. Unknowns within **A**, **B**, **C**, and **D** are assigned to the unknown parameter matrix, $\boldsymbol{\theta}$.

Equation 6 is the Fourier transform associated with *x(t)* for the finite time interval [0, *T*], a simple Euler approximation can be implemented resulting in equation 7.

$$\begin{aligned} \tilde{x}(\omega) &= \int_0^T x(t)e^{-j\omega}dt & (6) \\ \tilde{x}(\omega) &\approx \Delta t \sum_{i=0}^{N-1} x(i)e^{-j\omega\Delta t} & (7) \end{aligned}$$

where the complex number $j = \sqrt{-1}$, $\omega =$ is the angular frequency, *i* is the discrete time index, $\Delta t$ is the sampling interval, and $N$ + 1 is the total number of data points. The summation on the right in equation 7 is known as the Discrete Fourier Transform (DFT), $\tilde{X}(\omega)$:

$$\tilde{X}(\omega) = \sum_{i=0}^{N-1} x(i)e^{-j\omega\Delta t} \qquad (8)$$

thus equation 7 can be written as:

$$\tilde{x}(\omega) = \tilde{X}(\omega)\Delta t \qquad (9)$$

As equation 9 is effectively a first order Euler approximation [14] of equation 6 corrections such as those outlined by Morelli [15] can be made to account for the inaccuracies. However, by selecting a sampling rate much greater than the frequencies of interest (a small $\Delta t$) these corrections can be suitably neglected. Therefore, the Fourier transform for the linear model given in equations 3, and 4 can be expressed:

$$\begin{aligned} j\boldsymbol{\omega}\tilde{\boldsymbol{x}}(\boldsymbol{\omega}) &= \mathbf{A}\tilde{\boldsymbol{x}}(\boldsymbol{\omega}) + \mathbf{B}\tilde{\boldsymbol{u}}(\boldsymbol{\omega}) & (10) \\ \tilde{\boldsymbol{y}}(\boldsymbol{\omega}) &= \mathbf{C}\tilde{\boldsymbol{x}}(\boldsymbol{\omega}) + \mathbf{D}\tilde{\boldsymbol{u}}(\boldsymbol{\omega}) & (11) \end{aligned}$$

Provided that the state, outputs and inputs variables are measured the individual state or output (equation 10 and 11 respectively) can be formulated using the equation error method to estimate the stability and control derivatives in $\boldsymbol{A}, \boldsymbol{B}, \boldsymbol{C}$, and $\boldsymbol{D}$.

### D. Equation Error

It can be seen that the least squares cost function in the frequency domain for the $k^{th}$ state vector of equation 10 is:

$$J_k = \frac{1}{2}\sum_{n-1}^{m} \left| j\omega_n \tilde{x}_k(n) - \boldsymbol{A}_k\tilde{\boldsymbol{x}}(n) - \boldsymbol{B}_k\tilde{\boldsymbol{u}}(n) \right|^2 \qquad (12)$$

where $\tilde{\boldsymbol{x}}(n)$ and $\tilde{\boldsymbol{u}}(n)$ denote the Fourier transform of the state and control vectors for frequency $\omega_n$. Equation 11 can also be formulated as above for the relavent output equations. As rigid body aircraft dynamics typically lie below 2Hz, the *m* frequencies of interest in the summation of equation 12 were performed at 0.04Hz intervals from 0.01 - 2Hz, [16]. By neglecting the zero frequency which corresponds to the *trim* and measurement biases, the respective initial conditions no longer need to be estimated for the cost function. Now grouping the unknowns from $\boldsymbol{A}_k$ and $\boldsymbol{B}_k$ into $\boldsymbol{\theta}$, the standard least squares formulation for the complex data is:

$$\boldsymbol{Y} = \boldsymbol{X}\boldsymbol{\theta} + \boldsymbol{\epsilon} \qquad (13)$$

expanding the vectors:

$$\begin{aligned} \boldsymbol{Y}^T &\equiv [j\omega_1\tilde{x}_k(1), j\omega_2\tilde{x}_k(2), \ldots, j\omega_m\tilde{x}_k(m)] & (14) \\ \boldsymbol{X}^T &\equiv [\tilde{\boldsymbol{x}}(1)\ \tilde{\boldsymbol{u}}(1), \tilde{\boldsymbol{x}}(2)\ \tilde{\boldsymbol{u}}(2), \ldots, \tilde{\boldsymbol{x}}(m)\ \tilde{\boldsymbol{u}}(m)] & (15) \end{aligned}$$

and $\boldsymbol{\epsilon}$ is the complex equation error in the frequency domain; the cost function to be minimised is identical to that in equation 12 where "†" denotes the complex conjugate:

$$\begin{aligned} J &= \frac{1}{2}(\boldsymbol{Y} - \boldsymbol{X})^\dagger(\boldsymbol{Y} - \boldsymbol{X}) & (16) \\ \hat{\boldsymbol{\theta}} &= \left[Re(\boldsymbol{X}^\dagger\boldsymbol{X})\right]^{-1} Re(\boldsymbol{X}^\dagger\boldsymbol{Y}) & (17) \end{aligned}$$

and the estimated parameter covariance matrix is:

$$cov(\hat{\boldsymbol{\theta}}) \equiv E\left\{(\hat{\boldsymbol{\theta}} - \boldsymbol{\theta})(\hat{\boldsymbol{\theta}} - \boldsymbol{\theta})^T\right\} = \boldsymbol{\sigma}^2\left[Re(\boldsymbol{X}^\dagger\boldsymbol{X})\right]^{-1} \quad (18)$$

the equation error variance, $\boldsymbol{\sigma}^2$ is estimated from the residuals:

$$\boldsymbol{\sigma}^2 = \frac{1}{(m - n_p)}\left[(\boldsymbol{Y} - \boldsymbol{X}\hat{\boldsymbol{\theta}})^\dagger(\boldsymbol{Y} - \boldsymbol{X}\hat{\boldsymbol{\theta}})\right] \qquad (19)$$

where $n_p$ is the number of parameter elements in $\boldsymbol{\theta}$, and the parameter standard errors can be calculated by using equation 19 and then square rooting the diagonal elements of matrix $cov(\hat{\boldsymbol{\theta}})$ in equation 18.

### E. Real-time parameter estimation in frequency domain

Current real-time methods include: Recursive Least Squares (RLS), Extended Kalman Filter (EKF), and batch estimation methods (seen as sequential least squares) [17]. Identification in the cases of fault-detection and reconfigurable control requires immediate results (use RLS and EKF). In comparison for dynamic modelling, a near real-time capability is acceptable (use batch estimation method). Batch methods use strips of data at defined time intervals to approximate the time variation in the parameters and enable principally off-line methods such as the least squares technique to be used in a real-time setting. In order to gain the benefits of working in the frequency domain, a recursive finite Fourier transform (RFT) can be coupled with the sequential least squares.

With reference to the discrete Fourier transform (equation 8) the RFT for a specific frequency of interest $\boldsymbol{\omega}$, at sample time $i\Delta t$ can be related to the result at sample time ($i$ - 1)$\Delta t$ as follows:

$$X_i(\boldsymbol{\omega}) = X_{i-1}(\boldsymbol{\omega}) + x_i e^{-j\boldsymbol{\omega}i\Delta t} \qquad (20)$$

with

$$e^{-j\boldsymbol{\omega}\Delta t} = e^{-j\boldsymbol{\omega}t}e^{-j\boldsymbol{\omega}(i-1)\Delta t} \qquad (21)$$

Note that $e^{-j\boldsymbol{\omega}\Delta t}$ is constant for a given frequency $\omega$ and sampling interval of $\Delta t$. Therefore, equations 20 and 21 enable the data to be transformed for a given frequency with the use of one addition and two multiplications respectively. The time-domain data can be discarded as the RFT behaves as a memory, as the recursion proceeds results for each new sample are added to the overall information held in the constant $e^{-j\boldsymbol{\omega}\Delta t}$ term.

In order to improve the response of the PE to the most recent conditions a selective amnesia, $\lambda$, can be applied to the RFT as in equation 22 to remove past data. The effect of varying $\lambda$ from 0.95 - 1 can be seen as a type of windowing on the data, this is illustrated in figure 3, when $\lambda$ = 1, this results in the case of the general RFT where each data point is given equal weighting.

$$X_i(\boldsymbol{\omega}) = \lambda X_{i-1}(\boldsymbol{\omega}) + x_i e^{-j\boldsymbol{\omega} i\Delta t} \tag{22}$$

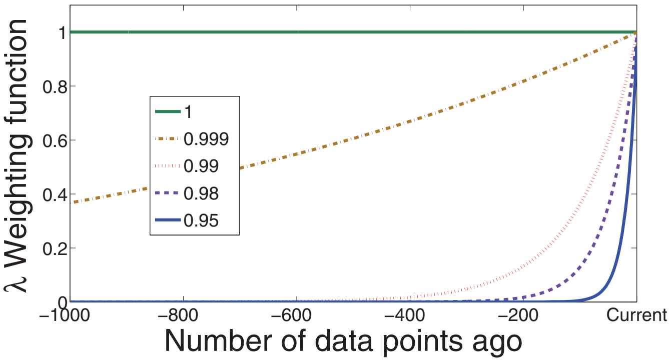

Fig. 3. Effective window of forgetting factor

For the implementation, data is recorded at 50 Hz and saved in csv format onboard the aircraft. Using Matlab the relevant state measurements for the desired mode are selected and then passed through the RFT of equations 22 and 21 at 1Hz. Subsequently the least-squares estimation is performed at 25Hz using equations 17 - 19. In order to prevent ill-conditioning when implementing equation 17 the first estimation uses 2 seconds of data to allow sufficient information to be gathered.

## III. Analysis

The flight trials were conducted at: 6045*ft* and 170*kt* (1843*m*, 87.5*m*/*s*) with a center of gravity at 30 % of the Mean Aerodynamic Chord. Two recordings were used, the first set for parameter estimation and the second set as a means of validation. Using *a priori* knowledge of the aircraft empirical estimates[1] of the concise derivatives were calculated for use as reference values. Tests were conducted with the forgetting factor varied from 0.95 - 1, the full results for $\lambda$ = 1 and an indicative set of results for $\lambda$ = 0.98 are presented below.

### A. Longitudinal

Trace plots for the reduced order longitudinal dynamics are shown in Figures 4 and 5, where the empirical estimates are plotted alongside the varying parameter estimates. The longitudinal dynamics were excited by closely coupling two elevator ($\eta$) impulses in a positive and negative direction, these are shown in the bottom subplot of each figure. The empirical (Emp) and final estimated (Est) values are listed in table I respectively; the Est values correspond to the finally estimated value at the end of each parameter trace plot and are indicated by a dot. The estimation results for the moment derivatives when a forgetting factor is used are presented in figure 6. Finally, figure 10 shows the prediction response of both sets of data from table I for the pitch rate response for the validation data set at the same flight condition.

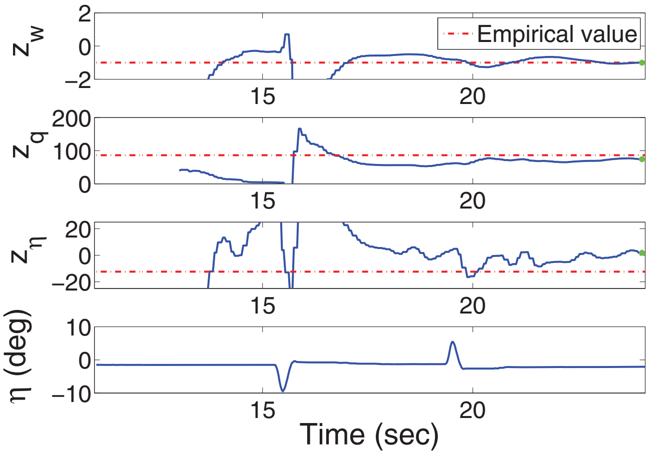

Fig. 4. SPPO: force derivatives

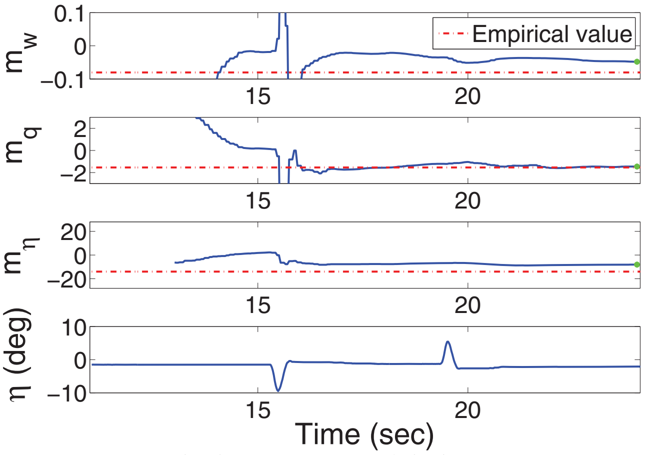

Fig. 5. SPPO: moment derivatives

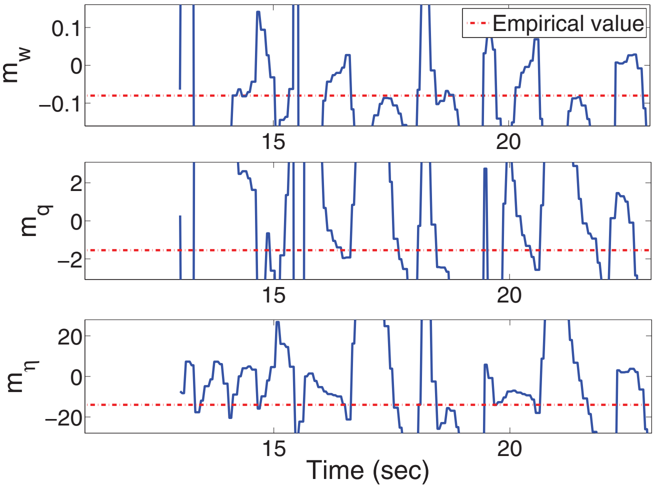

Fig. 6. SPPO: moment derivatives with $\lambda$ = 0.98

### B. Lateral

The lateral dynamic results are presented in a similar manner as above. In order to excite the lateral dynamics the yaw-damper needs to be disabled, then the pilot drives the mode by applying rudder ($\zeta$) doublets on the pedals as shown in the final subplot of figures 7 and 8.

[1] Using ESDU, a statistically significant data set and engineering judgment.

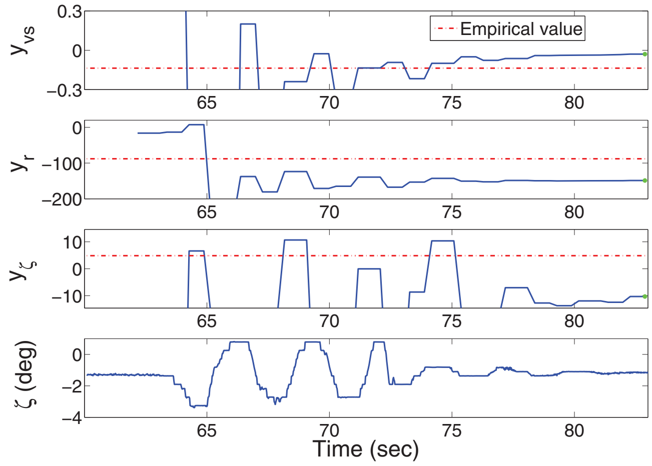

Fig. 7. DR: force derivatives

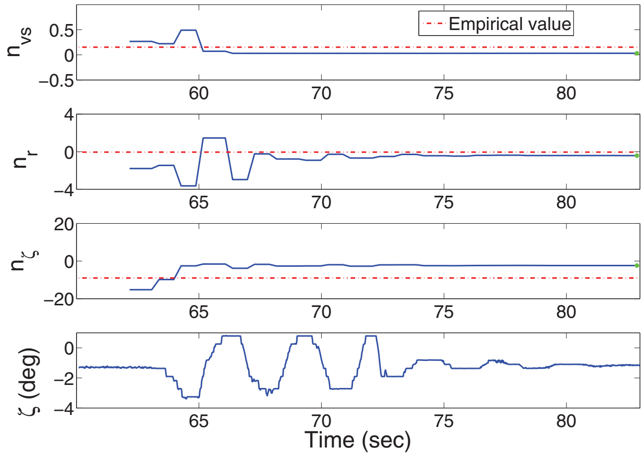

Fig. 8. DR: moment derivatives

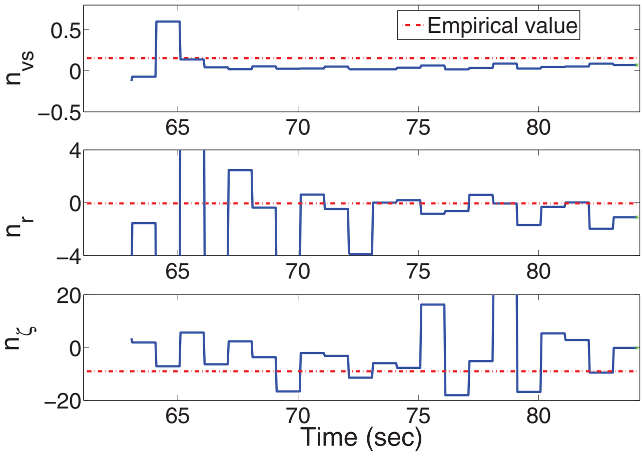

Fig. 9. DR: moment derivatives with $\lambda$ = 0.98

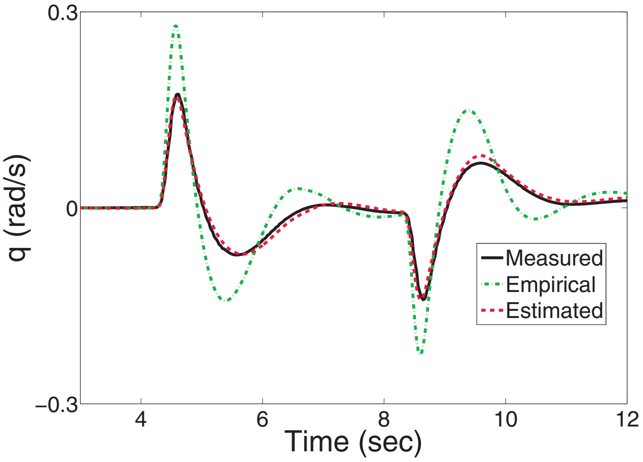

Fig. 10. SPPO: pitch rate validation plot

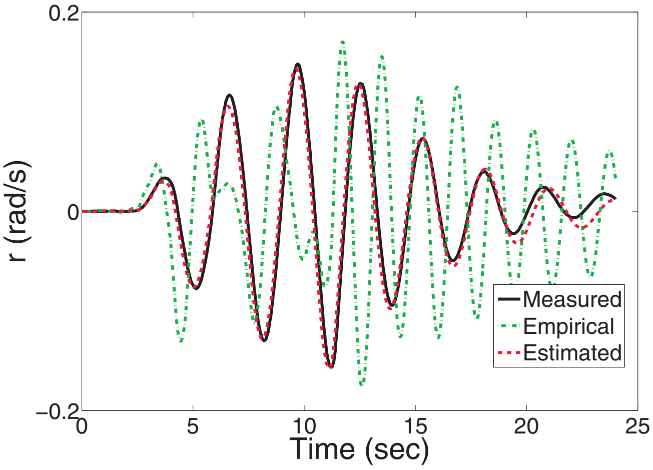

Fig. 11. DR: yaw rate validation plot

## IV. Discussion

Both sets of longitudinal derivatives established constant estimate values by the end of the 25 second data segment. In the case of the force derivatives (figure 4) all three parameters showed an improvement after the initial elevator deflection, and a small variability following the second deflection. Following the first input the moment derivatives (figure 5) were close to their steady state values with little variation following the second deflection. By contrast, the derivative estimates using the forgetting factor (figure 6), $\lambda$ = 0.98 showed no signs of convergence.

The pitch rate validation plot figure 10 demonstrates that the basic longitudinal dynamics have been captured with the reduced order model, and that the empirical estimates produce an under damped response as could be expected due to the informed approximations used. Referring to table I the majority of the empirical and estimated derivatives compare well. The exception is $z_\eta$ which has an incorrect sign and a reduced magnitude, however this is also highlighted as having the largest standard error of $\pm 19.599$. Nevertheless, it is important to note that the pitch damping term, $m_q$ (which is a key term for the SPPO mode) closely matches the empirical estimate and has a low standard error, $\pm 0.554$.

For the lateral case the force derivatives in figure 7 displayed a gradual improvement as the excitation manoeuvre progressed. In comparison the moment derivatives converged more rapidly to their respective final values (figure 8). Again

TABLE I
SPPO DERIVATIVES AND STANDARD ERRORS

| $\hat{\theta}$ | Emp | Est | $s$ |
|---|---|---|---|
| $z_w$ | -1.002 | -1.005 | 0.263 |
| $z_q$ | 86.170 | 74.362 | 13.125 |
| $z_\eta$ | -12.377 | 1.868 | 19.599 |
| $m_w$ | -0.080 | -0.048 | 0.011 |
| $m_q$ | -1.547 | -1.459 | 0.554 |
| $m_\eta$ | -14.002 | -8.078 | 0.826 |

TABLE II
DR DERIVATIVES AND STANDARD ERRORS

| $\hat{\theta}$ | Emp | Est | $s$ |
|---|---|---|---|
| $y_v$ | -0.137 | -0.029 | 0.051 |
| $y_r$ | -88.004 | -148.73 | 4.829 |
| $y_\zeta$ | 4.865 | -10.308 | 18.140 |
| $n_v$ | 0.153 | 0.031 | 0.001 |
| $n_r$ | -0.049 | -0.415 | 0.057 |
| $n_\zeta$ | -8.980 | -2.389 | 0.213 |

for the forgetting factor case, the moment derivatives are seen in figure 9 to exhibit a greater variation. For the validation data set the RFT estimated parameters produced a satisfactory yaw rate prediction in figure 11, with the empirical estimates resulting in an undamped response. In addition, a slightly under damped response can also be seen for the estimated derivatives after 20 seconds, this can possibly be attributed to unmodeled roll effects as the reduced order DR model is predominantly associated with yaw, but by definition DR is a coupled yaw-roll mode.

Comparing the DR derivatives in table II the majority of derivatives do not agree. Considering the two derivatives with the greatest standard errors ($s$), firstly, the estimated side force due to yaw rate derivative, $y_r$ is $\approx 1.7$ times greater than the empirical value. Secondly, the estimated side force due to rudder, $y_\zeta$ is of a different sign and order of magnitude in comparison to the empirical value. However, referring to the validation plot the DR mode dynamics would seem to have been captured, and therefore further investigation needs to be undertaken to explain the discrepancies that has been found.

Having analysed results for both the SPPO and DR modes the combined least squares in frequency domain RFT method is a promising solution for the online estimation problem. In the present work incorporating a forgetting factor with the RFT was found to be unsuitable particularly with the limited aircraft excitation manoeuvers available, as the removal of information content proved to be too sensitive. Finally, the ability to restrict the frequency range provides several benefits, firstly it significantly reduces the number of computations for the RFT and secondly, it acts as a filter to reduce the effects of the higher aero-elastic frequencies present (associated with the flexible airframe).

## V. CONCLUSION AND FUTURE WORK

A suitable methodology to address on-line estimation for a small UAV in the frequency domain has been outlined, in addition the results of trials using the Cranfield Jetstream-31 have been presented. Areas for further development lie in automatically stopping the batch estimation once the parameter estimates have converged to within a specified accuracy.

Furthermore, there exists the opportunity to enhance the way in which the flight data results are recorded, as the UAV flight envelope is opened. Results for runs in repeat conditions can be incorporated to the data set by taking advantage of the constant $e^{-j\omega\delta t}$ in the RFT and therefore continuing the recursion.

## ACKNOWLEDGEMENTS

This research was jointly funded as a CASE award by EPSRC and BAE Systems, and with the help of the Eric Beverley Bursary from The Worshipful Company of Coachmakers and Coach Harness Makers of London. The first author would like to thank Mr Chris Fielding, Dr Stephen Carnduff, and Dr Eugene Morelli for their time and advice.

*Abstract*— **In ship angular deformation measurement, Kalman filter used to estimate the deformation angle requires accurate dynamic flexure parameters. Traditionally, these dynamic flexure parameters are empirically set according to previous experience or determined from previously collected experimental data. Inevitably, the Kalman filter will perform poorly when the current application environment is differ with those used in the filter design. To overcome this problem, we propose an alternative online approach to estimate the dynamic flexure parameters based on the attitude difference measured by two laser gyro units. Specifically, the Tufts-Kumaresan (T-K) method is introduced to solve the unknown parameters of the dynamic flexure model from the computed attitude difference. Simulation results show that the proposed method can estimate the dynamic flexure parameters in real-time with a high degree of accuracy even in serious noise polluted conditions. A further advantage of the proposed approach is that it does not require *a priori* knowledge of the dynamic flexure characteristics.**

## I. Introduction

Ship angular deformation refers to the angular displacement existed between the shipboard sensors, such as the radar, optoelectronic detectors or missile coordinate frames, with the reference system of the master inertial navigation system (MINS) coordinate frame. The ship angular deformation consists of the static deformation component and the dynamic flexure, according to its time characteristics [1]. The static deformation is a time-invariant angular displacement due to installation errors. By contrast, the dynamic flexure is the structure flexure caused by the sea wave or wind induced loads, and it behaves like a random process. For high accurate tactical shipboard weapons or sensors, it is required to measure and compensate the angular deformation with respect to the MINS [2], [3]. Extensive works have focused on the ship angular deformation measurement problem in the past decades [4]–[7]. In particular, the inertial ship angular deformation measurement method is recognised as an efficient means to solve this problem, and it has attracted great attention in the recent years [8], [9].

The common procedure in inertial ship angular deformation measurement methods is to successively compute the attitude difference measured by two laser gyro units (LGUs) and to resolve the deformation angle through a real-time Kalman filter. In this procedure, the second-order Gauss-Markov process representing the dynamic flexure characteristics is adopted in Kalman filter design. Since the Kalman filter acts like an observer, the measurement accuracy is closely related to the accuracy of dynamic flexure model parameters, such as magnitude, frequency and damping ratio, employed in Kalman filters [6]. In general, the more accurate the dynamic flexure model parameters used, the more accurate the final deformation measurement is achieved [10]. Two existing approaches are usually adopted to determine the unknown parameters of the second-order Gauss-Markov process based dynamic flexure model: empirical method and statistical method. In an empirical method, as discussed in the works of [4], [8], the unknown parameters are simplified as the functions of the correlation time and variance of the dynamic flexure signal. By contrast, in a statistical method, as adopted by the reference [11], the unknown parameters are determined from the previously recorded dynamic flexure measurement data based on statistical estimation algorithms. Obviously, these two existing approaches do not meet the on-line requirements and operating environments, since the exact ship structure and actual work conditions will generally differ from those used in estimating the dynamic flexure model parameters.

It is highly advisable to adapt the dynamic flexure model parameters on-line so that the dynamic flexure parameters employed by the real-time Kalman filter match the specific working condition and environment. To achieve this goal, we propose an on-line parameter estimation method by utilising the attitude difference measured by two LGUs in order to estimate the dynamic flexure model parameters more accurately. More specifically, we assume that the dynamic flexure angles can be depicted by using the second-order Markov process, and the Tufts-Kumaresan (T-K) method [12] is then applied to solve the unknown parameters from the correlation function of the LGUs' attitude difference. Our simulation results obtained demonstrate that the parameters identified

using the T-K method have high accuracy. The proposed parameter estimation method requires no *a priori* knowledge of the dynamic flexure characteristics and it works well even under low signal to noise ratio (SNR) conditions.

## II. Ship Angular Deformation Measurement

Fig. 1 shows the schematic diagram of the ship angular deformation measurement system based on the attitude matching method [13]. Two LGUs, LGU$_1$ and LGU$_2$, are installed adjacent to the MINS and the shipboard sensor, respectively. Assume that LGU$_1$'s coordinates have been aligned with the the MINS frame ($m$-frame), while LGU$_2$'s coordinates have been aligned with sensor's frame ($s$-frame). As illustrated in Fig. 1, LGU$_1$ measures the Euler angle of the ship body motion $\boldsymbol{\xi}_m\big(\xi_{mx}, \xi_{my}, \xi_{mz}\big)$, and $\widehat{\boldsymbol{C}}_m^i$ is the corresponding direction cosine matrix (DCM) rotation from the $m$-frame to the inertial frame ($i$-frame), which is expressed in Eq. (1) at the bottom of this page. Similarly, $\boldsymbol{\xi}_s\big(\xi_{sx}, \xi_{sy}, \xi_{sz}\big)$ is the Euler angle measured by LGU$_2$, and $\widehat{\boldsymbol{C}}_s^i$ denotes the corresponding DCM rotation from the $s$-frame to the $i$-frame.

### A. Measurement Model

The measurement model is required to calculate the DCMs of $\widehat{\boldsymbol{C}}_m^i$ and $\widehat{\boldsymbol{C}}_s^i$ based on the angular information measured by LGU$_1$ and LGU$_2$. Let the calculated DCMs of $\widehat{\boldsymbol{C}}_m^i$ and $\widehat{\boldsymbol{C}}_s^i$ be

$$\widehat{\boldsymbol{C}}_m^i = \begin{bmatrix} C_{11} & C_{12} & C_{13} \\ C_{21} & C_{22} & C_{23} \\ C_{31} & C_{32} & C_{33} \end{bmatrix}, \widehat{\boldsymbol{C}}_s^i = \begin{bmatrix} C'_{11} & C'_{12} & C'_{13} \\ C'_{21} & C'_{22} & C'_{23} \\ C'_{31} & C'_{32} & C'_{33} \end{bmatrix}, \quad (2)$$

where $C_{ij}$ and $C'_{ij}$ denote the element of $\widehat{\boldsymbol{C}}_m^i$ and $\widehat{\boldsymbol{C}}_s^i$ at the $i$th row and $j$th column, respectively.

Then the attitude matching function for the ship angular deformation measurement is given by [13]

$$\boldsymbol{Z}_{dcm} = \boldsymbol{B}\boldsymbol{\varphi} - \boldsymbol{A}\boldsymbol{\phi}_0 + \boldsymbol{B}\big(\widehat{\boldsymbol{C}}_i^m \boldsymbol{\Psi}_m - \widehat{\boldsymbol{C}}_i^s \boldsymbol{\Psi}_s\big), \quad (3)$$

where $\boldsymbol{\varphi}$ is the total deformation angle between the LGU$_1$ and LGU$_2$, which includes a static component $\boldsymbol{\phi}_0$ and a dynamic component $\boldsymbol{\theta}$, and has the relation of $\boldsymbol{\varphi} = \boldsymbol{\phi}_0 + \boldsymbol{\theta}$. The measurement vector $\boldsymbol{Z}_{dcm}$ given in Eq. (3) is expressed by

$$\boldsymbol{Z}_{dcm} = \begin{bmatrix} C_{13}C'_{12} + C_{23}C'_{22} + C_{33}C'_{32} \\ C_{13}C'_{11} + C_{23}C'_{21} + C_{33}C'_{31} \\ C_{11}C'_{12} + C_{21}C'_{22} + C_{31}C'_{32} \end{bmatrix}, \quad (4)$$

and the coefficient matrices $\boldsymbol{A}$ and $\boldsymbol{B}$ are given by

$$\boldsymbol{A} = \begin{bmatrix} C_{33}C'_{22} - C_{23}C'_{32} & C_{13}C'_{32} - C_{33}C'_{12} & C_{23}C'_{12} - C_{13}C'_{22} \\ C_{33}C'_{21} - C_{23}C'_{31} & C_{13}C'_{31} - C_{33}C'_{11} & C_{23}C'_{11} - C_{13}C'_{21} \\ C_{31}C'_{22} - C_{21}C'_{32} & C_{11}C'_{32} - C_{31}C'_{12} & C_{21}C'_{12} - C_{11}C'_{22} \end{bmatrix} \text{ and } \boldsymbol{B} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{bmatrix}, \quad (5)$$

respectively, while $\boldsymbol{\Psi}_m$ anf $\boldsymbol{\Psi}_s$ are the attitude measurement errors induced by the gyro bias $\boldsymbol{\varepsilon}_0$ and the random walk noise $\boldsymbol{\varepsilon}_r$ in the LGU$_1$ and LGU$_2$, respectively, which can be determined by the following differential equations

$$\begin{cases} \dot{\boldsymbol{\Psi}}_m = -\widehat{\boldsymbol{C}}_m^i\big(\boldsymbol{\varepsilon}_{m0} + \boldsymbol{\varepsilon}_{mr}\big), \\ \dot{\boldsymbol{\Psi}}_s = -\widehat{\boldsymbol{C}}_s^i\big(\boldsymbol{\varepsilon}_{s0} + \boldsymbol{\varepsilon}_{sr}\big), \end{cases} \quad (6)$$

in which $\boldsymbol{\varepsilon}_{m0}$ and $\boldsymbol{\varepsilon}_{mr}$ denote the gyro bias and random walk noise of LGU$_1$, while $\boldsymbol{\varepsilon}_{s0}$ and $\boldsymbol{\varepsilon}_{sr}$ are the gyro bias and random walk noise of LGU$_2$.

As can be seen from Eq. (3), the measurement vector $\boldsymbol{Z}_{dcm}$ is linearised with respect to the ship angular deformation angle $\boldsymbol{\varphi}$. Furthermore, by using the dynamic flexure model in Kalman filter design, the ship angular deformation angle can be optimally estimated.

### B. Kalman Filter Design

It is well known that the Kalman filter offers the optimal result only when the system noise is white. However, in Eq. (3), the dynamic flexure angle is caused by the ship motion and wave loads vibration, whose frequency is closely correlated with the ship angular motion. If we use a white noise to depict the dynamic flexure in Kalman filter design, the result will be poor. The second-order Gauss-Markov process has been used extensively to model the dynamic flexure in many successful applications [4], [9], [13]. We therefore use this a second-order Gauss-Markov process for modelling the the dynamic flexure. The correlation function of the second-order Gauss-Markov process takes the form

$$R_{\theta_i}(\tau) = \sigma_i^2 \exp\big(-\alpha_i|\tau|\big)\big(\cos\beta_i\tau + \frac{\alpha_i}{\beta_i}\sin\beta_i|\tau|\big), \quad (7)$$

where the index $i$ indicates the $x$, $y$ or $z$ coordinate, $\tau$ is the time lag, and $\sigma_i^2$ is the variance of the $i$-coordinate component of the dynamic flexure, while $\alpha_i$ is the damping factor and $\beta_i$ is the circular frequency.

$$\widehat{\boldsymbol{C}}_m^i\big(\boldsymbol{\xi}_m\big) = \begin{bmatrix} \cos\xi_{my}\cos\xi_{mz} - \sin\xi_{mx}\sin\xi_{my}\sin\xi_{mz} & -\cos\xi_{mx}\sin\xi_{mz} & \sin\xi_{my}\cos\xi_{mz} + \sin\xi_{mx}\sin\xi_{mz}\cos\xi_{my} \\ \cos\xi_{my}\sin\xi_{mz} + \sin\xi_{mx}\sin\xi_{my}\cos\xi_{mz} & \cos\xi_{mx}\cos\xi_{mz} & \sin\xi_{my}\sin\xi_{mz} - \cos\xi_{my}\sin\xi_{mx}\cos\xi_{mz} \\ -\sin\xi_{my}\cos\xi_{mx} & \sin\xi_{mx} & \cos\xi_{mx}\cos\xi_{my} \end{bmatrix}. \quad (1)$$

The differential equation representing the ship dynamic flexure having the correlation function given in Eq. (7) can be written as

$$\ddot{\theta}_i + 2\alpha_i\dot{\theta}_i + b_i^2\theta_i = 2b_i\sigma_i\sqrt{\alpha_i}e_i(t), \tag{8}$$

where $b_i^2 = \alpha_i^2 + \beta_i^2$ is the square of the prevailing variation frequency and $e_i(t)$ is a Gaussian white noise with unit variance.

From Eqs. (3) to (8), we can derive the state function for the Kalman filter as follows

$$\dot{\boldsymbol{X}} = \boldsymbol{F}\boldsymbol{X} + \boldsymbol{w}, \tag{9}$$

where $\boldsymbol{X} \in \mathbb{R}^{21\times 1}$ is the state vector given by

$$\boldsymbol{X} = \begin{bmatrix}\boldsymbol{\phi}_0^{\mathrm{T}} & \boldsymbol{\theta}^{\mathrm{T}} & \dot{\boldsymbol{\theta}}^{\mathrm{T}} & \boldsymbol{\Psi}_m^{\mathrm{T}} & \boldsymbol{\Psi}_s^{\mathrm{T}} & \tilde{\boldsymbol{\varepsilon}}_m^{\mathrm{T}} & \tilde{\boldsymbol{\varepsilon}}_s^{\mathrm{T}}\end{bmatrix}^{\mathrm{T}}, \tag{10}$$

with $^{\mathrm{T}}$ denoting the vector or matrix transpose operator and the two gyro error vectors expressed by $\tilde{\boldsymbol{\varepsilon}}_m = \boldsymbol{\varepsilon}_{m0} + \boldsymbol{\varepsilon}_{mr}$ and $\tilde{\boldsymbol{\varepsilon}}_s = \boldsymbol{\varepsilon}_{s0} + \boldsymbol{\varepsilon}_{sr}$, respectively, while the state transition matrix $\boldsymbol{F} \in \mathbb{R}^{21\times 21}$ is given by

$$\boldsymbol{F} = \begin{bmatrix}\boldsymbol{O}_{3\times 3} & & \\ & \boldsymbol{F}_{6\times 6}^1 & \\ & & \boldsymbol{F}_{12\times 12}^2\end{bmatrix} \tag{11}$$

with $\boldsymbol{O}_{l\times m}$ denoting the $l \times m$ zero matrix,

$$\boldsymbol{F}_{6\times 6}^1 = \begin{bmatrix} & \boldsymbol{O}_{3\times 3} & & & \boldsymbol{I}_3 & \\ -b_x^2 & 0 & 0 & -2\mu_x & 0 & 0 \\ 0 & -b_y^2 & 0 & 0 & -2\mu_y & 0 \\ 0 & 0 & -b_z^2 & 0 & 0 & -2\mu_z \end{bmatrix} \tag{12}$$

and

$$\boldsymbol{F}_{12\times 12}^2 = \begin{bmatrix}\boldsymbol{O}_{3\times 6} & -\widehat{\boldsymbol{C}}_m^i & \boldsymbol{O}_{3\times 3} \\ \boldsymbol{O}_{3\times 6} & \boldsymbol{O}_{3\times 3} & -\widehat{\boldsymbol{C}}_s^i \\ & \boldsymbol{O}_{6\times 12} & \end{bmatrix}, \tag{13}$$

in which $\boldsymbol{I}_3$ is the $3 \times 3$ identity matrix. The system noise vector $\boldsymbol{w} \in \mathbb{R}^{21\times 1}$ has the covariance matrix

$$\begin{aligned} E\left[\boldsymbol{w}\boldsymbol{w}^{\mathrm{T}}\right] = \mathrm{diag}\Big\{&\boldsymbol{O}_{1\times 3}, 4b_x^2\sigma_x^2\alpha_x, 4b_y^2\sigma_y^2\alpha_y, 4b_z^2\sigma_z^2\alpha_z, \\ &\boldsymbol{O}_{1\times 9}, \left(\boldsymbol{\sigma}_{mr}^2\right)^{\mathrm{T}}, \left(\boldsymbol{\sigma}_{sr}^2\right)^{\mathrm{T}}\Big\}, \end{aligned} \tag{14}$$

where $E[\bullet]$ denotes the expectation operator and diag$\{\bullet\}$ the diagonal matrix, while $\boldsymbol{\sigma}_{mr}^2 \in \mathbb{R}^{3\times 1}$ whose elements are the three variances of the LGU$_1$'s gyro random walk noise vector $\boldsymbol{\varepsilon}_{mr}$ and $\boldsymbol{\sigma}_{sr}^2 \in \mathbb{R}^{3\times 1}$ contains the three variances of the LGU$_2$'s gyro random walk noise vector $\boldsymbol{\varepsilon}_{sr}$, respectively.

According to Eq. (3), the observation function is given by

$$\boldsymbol{Z}_{dcm} = \boldsymbol{H}\boldsymbol{X} + \boldsymbol{v}, \tag{15}$$

where $\boldsymbol{Z}_{dcm} \in \mathbb{R}^{3\times 1}$ is the observation vector, $\boldsymbol{v} \in \mathbb{R}^{3\times 1}$ is the measurement noise vector, and $\boldsymbol{H} \in \mathbb{R}^{3\times 21}$ is the observation matrix, which can be written as

$$\boldsymbol{H} = \begin{bmatrix}\boldsymbol{B} - \boldsymbol{A} & \boldsymbol{B} & \boldsymbol{O}_{3\times 3} & \boldsymbol{B}\widehat{\boldsymbol{C}}_i^m & -\boldsymbol{B}\widehat{\boldsymbol{C}}_i^s & \boldsymbol{O}_{3\times 6}\end{bmatrix}. \tag{16}$$

With the aid of the dynamic flexure model, the Kalman filter can accurately estimate the total deformation angle between the LGU$_1$ and LGU$_2$ frames. Let $\boldsymbol{\varphi}$ be the true deformation angle between LGU$_1$ and LGU$_2$, and $\widehat{\boldsymbol{\varphi}}$ be its estimate provided by the Kalman filter. The deformation estimate accuracy is determined by the error vector $\Delta\boldsymbol{\varphi}$ according to

$$\left[\Delta\boldsymbol{\varphi}\right]_{\mathrm{s-s}} = \boldsymbol{I}_3 - \boldsymbol{C}(\boldsymbol{\varphi})\boldsymbol{C}^{\mathrm{T}}(\widehat{\boldsymbol{\varphi}}), \tag{17}$$

where $\left[\Delta\boldsymbol{\varphi}\right]_{\mathrm{s-s}} \in \mathbb{R}^{3\times 3}$ denotes the skew-symmetric matrix of $\Delta\boldsymbol{\varphi}$ . From the above analysis, we can see that the deformation measuring accuracy depends on the accuracy of the dynamic flexure model parameters, $\alpha_i$, $\beta_i$ and $\sigma_i$, used in Eq. (12). Next, we present an on-line parameters estimation method based on the observation function of Eq. (3).

## III. Estimation of Dynamic Flexure Parameters

### A. Parameters Estimation Functions

Noting the relation $\boldsymbol{\varphi} = \boldsymbol{\phi}_0 + \boldsymbol{\theta}$, Eq. (3) can be rewritten as

$$\boldsymbol{Z}_{dcm} = \boldsymbol{Z}_{\phi_0} + \boldsymbol{Z}_{\theta} + \boldsymbol{Z}_{\psi}, \tag{18}$$

in which

$$\boldsymbol{Z}_{\phi_0} = (\boldsymbol{B} - \boldsymbol{A})\boldsymbol{\phi}_0, \tag{19}$$

$$\boldsymbol{Z}_{\theta} = \boldsymbol{B}\boldsymbol{\theta}, \tag{20}$$

$$\boldsymbol{Z}_{\psi} = \boldsymbol{B}\big(\widehat{\boldsymbol{C}}_i^m\boldsymbol{\Psi}_m - \widehat{\boldsymbol{C}}_i^s\boldsymbol{\Psi}_s\big). \tag{21}$$

The validity of Eq. (18) rests on the assumption that $\boldsymbol{\varphi}$ is small, which is generally true in reality.

The static component $\boldsymbol{\phi}_0$ in practice is compensated to within several milliradians using the course estimate results. In addition, $\big(\boldsymbol{B} - \boldsymbol{A}\big) = \boldsymbol{I}_3 - \widehat{\boldsymbol{C}}_i^m\widehat{\boldsymbol{C}}_s^i$ is very small. Taken into account these conditions, $\boldsymbol{Z}_{\phi_0}$ in Eq. (18) may be removed.

The attitude error term $\boldsymbol{Z}_{\psi}$ is induced by the gyro errors, including gyro bias and gyro random walk noise. According to the reference [14], the typical frequency of dynamic flexure ranges from 0.1 Hz to 0.25 Hz, while the frequency of the gyro noise induced attitude error is less than 0.01 Hz [15], which is far lower than the dynamic flexure frequency. Therefore, we can remove $\boldsymbol{Z}_{\psi}$ from Eq. (18) via a High-pass filter. The filtering process can be expressed by

$$\tilde{\boldsymbol{Z}}_{dcm} \approx \boldsymbol{F}^{-1}\big[\boldsymbol{H}_h(\omega)\boldsymbol{Z}_{dcm}(\omega)\big] \approx \boldsymbol{B}\boldsymbol{\theta}, \tag{22}$$

where $\boldsymbol{F}^{-1}[\bullet]$ denotes the inverse Fourier transform, $\boldsymbol{H}_h(\omega)$ is the transfer function of the High-pass filter, and $\boldsymbol{Z}_{dcm}(\omega)$ is the frequency-domain transformation of $\boldsymbol{Z}_{dcm}$. The correlation function of $\tilde{\boldsymbol{Z}}_{dcm}$ is given by

$$\begin{aligned} \boldsymbol{R}_Z(\tau) &= \langle\tilde{\boldsymbol{Z}}_{dcm}(t), \tilde{\boldsymbol{Z}}_{dcm}(t+\tau)\rangle \\ &= \langle\boldsymbol{B}\boldsymbol{\theta}(t), \boldsymbol{B}\boldsymbol{\theta}(t+\tau)\rangle = \langle\boldsymbol{\theta}(t), \boldsymbol{\theta}(t+\tau)\rangle, \end{aligned} \tag{23}$$

with $\langle\boldsymbol{\theta}(t), \boldsymbol{\theta}(t+\tau)\rangle$ denoting the correlation function of $\boldsymbol{\theta}(t)$.

Eq. (23) establishes an approximated relation of the dynamic flexure with the attitude measurement difference. By Comparing Eq. (23) with Eq. (7), the parameters of the dynamic flexure model, $\alpha_i$, $\beta_i$ and $\sigma_i$, can be determined.

### *B. Tufts-Kumaresan Method*

We apply the T-K method [12] to estimate the unknown parameters in Eq. (7) based on the measurement values of Eq. (23). The T-K method is a common choice to resolve closely spaced sinusoids, particularly when the data length is short and the SNR value is small. The T-K algorithm [12] is briefly summarised below.

Give the $N$ samples of a sequence $y(n)$, which consists of a sum of the $M$ exponentially damped sinusoidal signals

$$y(n) = \sum_{l=1}^{M} a_l \exp(s_l n) + q_n,\ n = 1, 2, \cdots, N, \tag{24}$$

where $a_l$ is the complex amplitude of the damped mode $\exp(s_l) = \exp\big(-\alpha_l + \mathrm{j}\beta_l\big)$ with $\alpha_l > 0$, and $q_n$ is the unknown white noise with variance $\sigma_q^2$. Using the complex conjugate data to set up the backward prediction function

$$\boldsymbol{A}\boldsymbol{b} = \boldsymbol{h}, \tag{25}$$

with

$$\boldsymbol{A} = \begin{bmatrix} y^*(2) & y^*(3) & \cdots & y^*(L+1) \\ y^*(3) & y^*(4) & \cdots & y^*(L+2) \\ \vdots & \vdots & \vdots & \vdots \\ y^*(N-L+1) & y^*(N-L+2) & \cdots & y^*(N) \end{bmatrix}, \tag{26}$$

$$\boldsymbol{b} = \begin{bmatrix} b_1 & b_2 & \cdots & b_L \end{bmatrix}^{\mathrm{T}}, \tag{27}$$

$$\boldsymbol{h} = \begin{bmatrix} y^*(1) & y^*(2) & \cdots & y^*(N-L) \end{bmatrix}^{\mathrm{T}}. \tag{28}$$

The prediction error filter polynomial

$$B(z) = 1 + b_1 z^{-1} + b_2 z^{-2} + \cdots + b_L z^{-L}, \tag{29}$$

has the zeros at $\exp\big(-s_l^*\big)$, $1 \le l \le M$, if $L$ is chosen to satisfy the inequality $M \leqslant L \leqslant N - M$. The roots of the polynomial of Eq. (29) yields the set of $M$ zeros, from which the $M$ damped modes $\exp\big(s_l\big)$, $1 \le l \le M$, can be determined. Then the amplitudes $a_l$ can easily be estimated based on the data set $\{y(n)\}$ described by Eq. (24) according to the least squares principle.

By substituting the discrete correlation results of Eq. (23) into Eq. (24), the parameters of the dynamic flexure model, $\alpha_i$, $\beta_i$ and $\sigma_i$, can be directly estimated by applying the T-K algorithm. Note that, the solution of Eq. (24) for real signal will give pairs of roots, $\exp\big(-s_l^*\big)$ and $\exp\big(-s_l\big)$, $1 \le l \le M$, and we simply use one root from each pair to calculate the dynamic flexure parameters.

## IV. Simulation Results

The schematic diagram of the gyro signal sample generation, parameter estimation and ship deformation angle estimation is shown in Fig. 2.

### *A. Simulation System Setup*

According to our experimental experience, the ship angular motion can be simplified as a random process, which can also be depicted as a second-order Gauss-Markov process

$$R_{\xi_i}(\tau) = \sigma_{\xi_i}^2 \exp\big(-\alpha_{\xi_i}|\tau|\big)\Big(\cos\beta_{\xi_i}\tau + \frac{\alpha_{\xi_i}}{\beta_{\xi_i}}\sin\beta_{\xi_i}|\tau|\Big), \tag{30}$$

where $i$ again denotes the $x$, $y$ or $z$ coordinate, while $\sigma_{\xi_i}^2$, $\alpha_{\xi_i}$ and $\beta_{\xi_i}$ are the variance, damping factor and circular frequency, respectively, of the $i$ coordinate of the ship attitude angle. We assume that during the simulation the parameters $\sigma_{\xi_i}^2$, $\alpha_{\xi_i}$ and $\beta_{\xi_i}$ are time invariant. Table I lists the simulation parameters of the ship attitude angles used. The values of $\beta_{\xi_i}$ and $\alpha_{\xi_i}$ are taken from our previous real-data identification results, while the values of $\sigma_{\xi_i}$ are set according to our experimental experience.

the variances $\sigma_i$, damping factors $\alpha_i$ and frequencies $\beta_i$ used to simulate the dynamic flexure are time invariant, whose values are list in Table II. The damping factors and frequencies are identified from our real measurement data in sea trials, while the values of the variances are set according to our empirical experience to reflect certain level of real sea condition. Additionally, in order to reflect the real measurement environment, we add a Gaussian white noise $\varsigma_i(t)$ of variance $\sigma^2_{\varsigma_i}$ to the dynamic flexure signal $\theta_i$. The SNR of the dynamic flexure signal is then defined by

$$\mathrm{SNR}_i = 10 \log_{10} \frac{\sigma_i^2}{\sigma^2_{\varsigma_i}}, \tag{31}$$

where again $i$ indicates the $x$, $y$ or $z$ coordinate. We assume that the static deformation angle after the initial compensation is $[3.5 \text{ mrad } 3.5 \text{ mrad } 3.5 \text{ mrad}]$.

The parameters of the bias error vector $\boldsymbol{\varepsilon}_0$ and the random walk noise vector $\boldsymbol{\varepsilon}_r$ for the gyros are list in Table III. The simulated LGU$_1$ and LGU$_1$ gyro outputs are processed to derive the attitude values of $\widehat{\boldsymbol{C}}^i_m$ and $\widehat{\boldsymbol{C}}^i_s$, which are then used to estimate the dynamic flexure parameters as well as used by a Kalman filter to compute the deformation angle $\boldsymbol{\varphi}$.

TABLE III

PARAMETERS OF THE GYRO NOISES USED IN THE SIMULATION SYSTEM, WHERE WN STD DENOTES THE STANDARD DEVIATION OF THE WHITE NOISE COMPONENT.

| | LGU$_1$ | | LGU$_2$ | |
|---|---|---|---|---|
| | Bias<br>$\boldsymbol{\varepsilon}_{m0}$<br>(deg/hr) | Random walk<br>$\boldsymbol{\varepsilon}_{mr}$'s WN STD<br>$(\deg/\sqrt{\text{hr}})$ | Bias<br>$\boldsymbol{\varepsilon}_{s0}$<br>(deg/hr) | Random walk<br>$\boldsymbol{\varepsilon}_{sr}$'s WN STD<br>$(\deg/\sqrt{\text{hr}})$ |
| X | 0.005 | 0.002 | 0.02 | 0.005 |

| Z | 0.005 | 0.002 | 0.02 | 0.005 |

## B. Results and Analysis

The total data length for the ship deformation measurement was $T = 600$ s with the sample frequency of 20 Hz. The cut-off frequency for the High-pass filter used was set to 0.05 Hz. To better compensate the approximation error induced by the static deformation angle $\boldsymbol{\phi}_0$, we ran the T-K algorithm twice in parameters estimation. Specifically, in the first run, we obtained an improved estimate $\widehat{\boldsymbol{\phi}}_0$, and then fed back this value to compensate the error term $\boldsymbol{Z}_{\phi_0}$. The second run's result was accepted as our estimate. All the results presented were obtained by averaging over 100 independent trials in the presence of the randomly generated noise for simulating the ship attitude, dynamic flexure and gyro noise signals.

TABLE IV

MEANS AND STANDARD DEVIATIONS OF THE ESTIMATED DYNAMIC FLEXURE PARAMETERS OBTAINED UNDER THE CONDITION OF $\sigma^2_{\varsigma_i} = 0$, GIVEN $T = 600$ S, $N = 20$ S, $L = 6$ S AND $M = 2$.

| | Magnitude<br>$\sigma_i$ (mrad) | Frequency<br>$\beta_i/2\pi$ (Hz) | Damping factor<br>$\alpha_i$ (s$^{-1}$) |
|---|---|---|---|
| Pitch | 0.3950 (0.0064) | 0.1892 (0.0041) | 0.1272 (0.0252) |
| Roll | 0.6722 (0.0089) | 0.1685 (0.0039) | 0.1054 (0.0188) |
| Yaw | 0.4961 (0.0075) | 0.1798 (0.0034) | 0.1013 (0.0183) |

The performance of the T-K method depends on its algorithmic parameters, $M$, $N$ and $L$ [12]. We used $M = 2$ for Eq. (25), which yielded a pair of roots for every damping mode. Appropriate values for $N$ and $L$ were determined by extensive experiments, and they were found to be $L = 6$ s or 120 samples, and $N = 20$ s or 400 samples.

Table IV lists the means and standard deviations (in bracket) of the estimation results for the parameters $\alpha_i$, $\beta_i$ and $\sigma_i$ at the condition of $\sigma^2_{\varsigma_i} = 0$. Comparing with the true values given in Table II, it can be seen that the parameter estimates are very accurate. The ship angular deformation measurement results based on the identified dynamic flexure model are shown in Table V, where it can be observed that a high accurate measurement is achieved.

TABLE V

PERFORMANCE OF THE KALMAN FILTER BASED SHIP ANGULAR DEFORMATION MEASUREMENT OBTAINED BASED ON THE DYNAMIC FLEXURE MODEL IDENTIFIED UNDER THE CONDITION OF $\sigma^2_{\varsigma_i} = 0$.

| | Mean and standard deviation of true deformation angle (mrad) | Mean and standard deviation of KF estimated deformation angle (mrad) | Mean and standard deviation of KF based measurement error (mrad) |
|---|---|---|---|
| Pitch | 3.4981 (0.4267) | 3.5179 (0.5525) | 0.2626 (0.2005) |
| Roll | 3.4792 (0.7209) | 3.5131 (0.7776) | 0.3259 (0.2369) |
| Yaw | 3.5027 (0.4840) | 3.5483 (0.5626) | 0.1944 (0.1382) |

We next investigated the accuracy of the dynamic flexure parameter estimate and the Kalman filter performance under different SNR conditions. Fig. 3 shows the mean parameters estimation errors as well the average deformation measurement errors given different SNR values. As can be seen from Fig. 3 (a) to (c), the parameters, $\alpha_i$, $\beta_i$ and $\sigma_i$, can be estimated to a high degree of accuracy while the average parameter estimation errors and their error bars were similar across the range of the SNR values tested, except for the yaw magnitude error at the SNR value of 5 dB. This demonstrates the robustness of the algorithm under the noise polluted shipboard environment. However, the estimates of the magnitudes $\sigma_i$ and frequencies $\beta_i$ were slightly biased. This bias may be caused by removing the term $\boldsymbol{Z}_{\phi_0}$ as well as using high-pass filtering to remove the attitude error term $\boldsymbol{Z}_{\psi}$ in Eq. (18). By using the estimated dynamic flexure parameters, the average deformation measurement errors and their corresponding standard deviations are depicted in Fig. 3 (d). The results demonstrate that the Kalman filter is capable of achieving high accurate ship angular deformation measurement under serious noise polluted environments.

# V. CONCLUSIONS

An efficient on-line dynamic flexure parameter estimation method has been proposed for the ship angular deformation measurement system based on the attitude difference provided by two LGUs measures. The relationship between the attitude difference correlation function and that of the second-order Gauss-Markov process representing the dynamic flexure model has been presented, and the Tufts-Kumaresan method has been applied to identify the unknown dynamic flexure model

parameters. From the extensive simulation results, it has been shown that the proposed model parameter estimation method is capable of obtaining accurate estimates of the unknown dynamic flexure parameters for the application of accurate ship deformation measurement. Our approach does not require *a priori* knowledge of the dynamic flexure characteristics, and it equips the ship angular deformation measurement system with the ability to adapt to various work conditions. Our future work will study how to reduce or remove the parameter estimate bias in the T-K based model parameters estimation algorithm.

# Singularly Impulsive Dynamical Systems with time delay: Mathematical Model and Stability

Nataša A. Kablar, Vlada Kvrgić,
*Lola Institute, Kneza Viseslava 70a, Belgrade 11000, Serbia*
nkablar.ae01@gtalumni.org, vlada.kvrgic@li.rs

**Abstract** - *In this paper we introduce new class of system, so called singularly impulsive or generalized impulsive dynamical systems with time delay. Dynamics of this system is characterized by the set of differential and difference equations with time delay, and algebraic equations. They represent the class of hybrid systems, where algebraic equations represent constraints that differential and difference equations with time delay need to satisfy. In this paper we present model, assumptions on the model, two classes of singularly impulsive dynamical systems with delay - time dependenet and state dependent. Further, we present Lyapunov and asymptotic stability theorems for nonlinear time-dependent and state-dependent singularly impulsive dynamical systems with time delay.*

## I. Introduction

Modern complex engineering systems as well as biological and physiological systems typically possess a multi-echelon hierarchical hybrid architecture characterized by continuous-time dynamics at the lower levels of hierarchy and discrete-time dynamics at the higher levels of the hierarchy. Hence, it is not surprising that hybrid systems have been the subject of intensive research over the past recent years (see Branicky et al. (1998), Ye et al. (1998 b), Haddad, Chellaboina and Kablar (2001a-b)). Such systems include dynamical switching systems Branicky (1998), Leonessa et al. (2000), nonsmooth impact and constrained mechanical systems, Back et al. (1993), Brogliato (1996), Brogliato et al. (1997), biological systems Lakshmikantham et al. (1989), demographic systems Liu (1994), sampled-data systems Hagiwara and Araki (1988), discrete-event systems Passino et al. (1994), intelligent vehicle/highway systems Lygeros et al. (1998) and flight control systems, etc. The mathematical descriptions of many of these systems can be characterized by impulsive differential equations, Simeonov and Bainov (1985), Liu (1988), Lakshmikantham et al. (1989, 1994), Bainov and Simeonov (1989, 1995), Kulev and Bainov (1989), Lakshmikantham and Liu (1989), Hu et al. (1989), Samoilenko and Perestyuk (1995), Haddad, Chellaboina and Kablar (2001a-b). Impulsive dynamical systems can be viewed as a subclass of hybrid systems.

Motivated by the results on impulsive dynamical systems presented in Haddad, Chellaboina, and Kablar (2001, 2005), the authors previous work on singular or generalized systems, and results on singularly impulsive dynamical systems published in Kablar(2003, 2010) we presented new class of *singularly impulsive* or *generalized impulsive dynamical systems with time delay*. It presents novel class of hybrid systems and generalization of impulsive dynamical systems to incorporate singular nature of the systems and time delays. Extensive applications of this class of systems can be found in contact problems and in hybrid systems.

We present mathematical model of the singularly impulsive dynamical systems with time delay. We show how it can be viewed as general systems from which impulsive dynamical systems with time delay, singular continuous-time systems with time delay and singular dicrete-time systems with time delay, as well as without time delay,follow. Then we present Assumptions needed for the model and the division of this class of systems to time-dependent and state-dependent singularly impulsive dynamical systems with time delay with respect to the resetting set. Finally, we draw some conclusions and define future work.

In this paper for the class of nonlinear singularly impulsive dynamical systems with time delay we develop Lyapunov and asymptotic stability results. Results are further specialized to linear case. Note that for addressing the stability of the zero solution of a singularly impulsive dynamical system the usual stability definitions are valid. Then we draw some conclusions and define future work.

At first, we establish definitions and notations. Let $\mathbb{R}$ denote the set of real numbers, let $\mathbb{R}^n$ denote the set of $n \times 1$ real column vectors, let $\mathcal{N}$ denote the set of nonnegative integers, and let $I_n$ or $I$ denote the $n \times n$ identity matrix. Furthermore, let $\partial\mathcal{S}, \dot{\mathcal{S}}, \bar{\mathcal{S}}$ denote the boundary, the interior, and a closure of the subset $\mathcal{S} \subset \mathbb{R}^n$, respectively. Finally, let $\mathrm{C}^0$ denote the set of continuous functions and $\mathrm{C}^{\mathrm{r}}$ denote the set of functions with $r$ continuous derivatives.

## II. Mathematical Model of Singularly Impulsive Dynamical Systems with Time Delay

A singularly impulsive dynamical system with delay consists of three elements:

1. A possibly singular continuous-time dynamical equation with time delay, which governs the motion of the system between resetting events;
2. A possibly singular difference equation with time delay, which governs the way the states are instantaneously changed when a resetting occurs; and

3. A criterion for determining when the states of the system are to be reset.

Mathematical model of these systems is described with

$$E_{\rm c}\dot{x}(t) = f_{\rm c}(x(t,\tau)) + G_{\rm c}(x(t,\tau))u_{\rm c}(t), \quad (t, x(t,\tau), u_{\rm c}(t)) \notin \mathcal{S}, \tag{II.1}$$

$$E_{\rm d}\triangle x(t) = f_{\rm d}(x(t,\tau)) + G_{\rm d}(x(t,\tau))u_{\rm d}(t), \quad (t, x(t,\tau), u_{\rm c}(t)) \in \mathcal{S}, \tag{II.2}$$

$$y_{\rm c}(t) = h_{\rm c}(x(t,\tau)) + J_{\rm c}(x(t,\tau))u_{\rm c}(t), \quad (t, x(t,\tau), u_{\rm c}(t)) \notin \mathcal{S}, \tag{II.3}$$

$$y_d(t) = h_{\rm d}(x(t,\tau) + J_{\rm d}(x(t,\tau))u_{\rm d}(t), \quad (t, x(t,\tau), u_{\rm c}(t)) \in \mathcal{S}, \tag{II.4}$$

where $t \geq 0$, $\tau > 0$, $x(0) = x_0$, $x(t,\tau) \in \mathcal{D} \subset \mathbb{R}^{\ltimes} \times \mathbb{N}$, $\mathcal{D}$ is an open set with $0 \in \mathcal{D}$, $u_{\rm c} \in \mathcal{U}_{\rm c} \subset \mathbb{R}^{\gtrdot_{\rm c}}$, $u_{\rm d}(t_k) \in \mathcal{U}_{\rm d} \subset \mathbb{R}^{\gtrdot_{\rm d}}$, $t_k$ denotes $k^{\rm th}$ instant of time at which $(t, x(t,\tau), u_{\rm c}(t))$ intersects $\mathcal{S}$ for a particular trajectory $x(t,\tau)$ and input $u_{\rm c}(t), y_{\rm c}(t) \in \mathbb{R}^{\lessdot_{\rm c}}, y_{\rm d}(t_k) \in \mathbb{R}^{\lessdot_{\rm d}}$, $f_{\rm c} : \mathcal{D} \to \mathbb{R}^{\ltimes}$ is Lipschitz continuous and satisfies $f_{\rm c}(0) = 0$, $G_{\rm c} : \mathcal{D} \to \ltimes \times \gtrdot_{\rm c}$, $f_{\rm d} : \mathcal{D} \to \mathbb{R}^{\ltimes}$ is continuous and satisfies $f_{\rm d}(0) = 0$, $G_{\rm d} : \mathcal{D} \to \mathbb{R}^{n \times m_{\rm d}}$, $h_{\rm c} : \mathcal{D} \to \mathbb{R}^{l_{\rm c}}$ and satisfies $h_{\rm c}(0) = 0$, $J_{\rm c} : \mathcal{D} \to \mathbb{R}^{l_{\rm c} \times m_{\rm c}}$, $h_{\rm d} : \mathcal{D} \to \mathbb{R}^{l_{\rm d}}$ and satisfies $h_{\rm d}(0) = 0$, $J_{\rm d} : \mathcal{D} \to \mathbb{R}^{l_{\rm d} \times m_{\rm d}}$, and $\mathcal{S} \subset [0,\infty) \times \mathbb{R}^n \times \mathcal{U}_{\rm c}$ is the *resetting set*. Here, as in Haddad, Chellaboina, and Kablar (2001a) we assume that $u_{\rm c}(\cdot)$ and $u_{\rm d}(\cdot)$ are restricted to the class of *admissible* inputs consisting of measurable functions $(u_{\rm c}(t), u_{\rm d}(t)) \in \mathcal{U}_{\rm c} \times \mathcal{U}_{\rm d}$ for all $t \geq 0$ and $k \in \mathcal{N}_{[0,t)} \equiv k : 0 \leq t_k < t$, where the constraint set $\mathcal{U}_{\rm c} \times \mathcal{U}_{\rm d}$ is given with $(0,0) \in \mathcal{U}_{\rm c} \times \mathcal{U}_{\rm d}$. We refer to the differential equation (II.1) as the *continuous-time dynamics with time delay*, and we refer to the difference equation (II.2) as the *resetting law*.

Matrices $E_{\rm c}$, $E_{\rm d}$ may be singular matrices. In case $E_{\rm c} = I$, $E_{\rm d} = I$, and $\tau = 0$ (II.1)–(II.4) represent standard impulsive dynamical systems described in Haddad, Chellaboina, and Kablar (2001a), and Haddad, Kablar, and Chellaboina (2000, 2005), where stability, dissipativity, feedback interconnections, optimality, robustness, and disturbance rejection has been analyzed. In absence of discrete dynamics they specialize to singular continuous-time systems, with further specialization $E_{\rm c} = I$ to standard continuous-time systems. If only discrete dynamics is present they specialize to singular discrete-time systems, with further specialization $E_{\rm d} = I$ to standard discrete-time systems.

In case $E_{\rm c} = I$, $E_{\rm d} = I$, and $\tau \neq 0$, (II.1)–(II.4) represent standard impulsive dynamical systems with time delay. In absence of discrete dynamics they specialize to singular continuous-time systems with time delay, with further specialization $E_{\rm c} = I$ to standard continuous-time systems with time delay. If only discrete dynamics is present they specialize to singular discrete-time systems with time delay, with further specialization $E_{\rm d} = I$ to standard discrete-time systems with time delay.

Therefore, theory of the singularly impulsive or generalized impulsive dynamical systems with time delay once developed, can be viewed as a generalization of the singular and impulsive dynamical system with time delay theory, unifying them into more general new system theory.

In what follows is given basic setting and division of this class of systems with respect to the definition of the resetting sets, accompanied with adequate assumptions needed for the model.

We make the following additional assumptions:

A1. $(0, x_0, u_{\rm c0}) \notin \mathcal{S}$, where $x(0) = x_0$ and $u_{\rm c}(0) = u_{\rm c0}$, that is, the initial condition is not in $\mathcal{S}$.

A2. If $(t, x(t,\tau), u_{\rm c}(t)) \in \bar{\mathcal{S}} \backslash \mathcal{S}$ then there exists $\epsilon > 0$ such that, for all $0 < \delta < \epsilon$, $s(t+\delta; t, x(t,\tau), u_{\rm c}(t+\delta)) \notin \mathcal{S}$.

A3. If $(t_k, x(t_k), u_{\rm c}(t_k)) \in \partial S \cap \mathcal{S}$ then there exists $\epsilon > 0$ such that, for all $0 < \delta < \epsilon$ and $u_{\rm d}(t_k) \in \mathcal{U}_{\rm d}$, $s(t_k + \delta; t_k, E_{\rm d}x(t_k) + f_{\rm d}(x(t_k)) + G_{\rm d}(x(t_k))u_{\rm d}(t_k), u_{\rm c}(t_k+\delta)) \notin \mathcal{S}$.

A4. We assume consistent initial conditions (and prior and after every resetting).

Assumption A1 ensures that the initial condition for the resetting differential equation (II.1), (II.2) is not a point of discontinuity, and this assumption is made for convenience. If $(0, x_0, u_{\rm c0}) \in \mathcal{S}$, then the system initially resets to $E_{\rm d}x_0^+ = E_{\rm d}x_0 + f_{\rm d}(x_0) + G_{\rm d}(x_0)u_{\rm d}(0)$ which serves as the initial condition for the continuous dynamics (II.1). It follows from A3 that the trajectory then leaves $\mathcal{S}$. We assume in A2 that if a trajectory reaches the closure of $\mathcal{S}$ at a point that does not belong to $\mathcal{S}$, then the trajectory must be directed away from $\mathcal{S}$, that is, a trajectory cannot enter $\mathcal{S}$ through a point that belongs to the closure of $\mathcal{S}$ but not to $\mathcal{S}$. Finally, A3 ensures that when a trajectory intersects the resetting set $\mathcal{S}$, it instantaneously exits $\mathcal{S}$, see Figure 1. We make the following remarks.

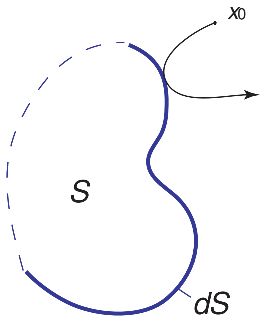

**Figure 1.** Resetting Set.

**Remark II.1.** *It follows from A3 that resetting removes the pair $(t_k, x_k, u_{\rm c}(t_k))$ from the resetting set $\mathcal{S}$. Thus, immediately after resetting occurs, the continuous-time dynamics (II.1), and not the resetting law (II.2), becomes the active element of the singularly impulsive dynamical system.*

**Remark II.2.** *It follows from A1-A3 that no trajectory can intersect the interior of $\mathcal{S}$. According to A1, the trajectory $x(t)$ begins outside the set $\mathcal{S}$. Furthermore, it follows from A2 that a trajectory can only reach $\mathcal{S}$ through a point belonging to both $\mathcal{S}$ and its boundary. Finally, from A3, it follows that if a trajectory reaches a point $\mathcal{S}$ that is on the boundary of $\mathcal{S}$, then the trajectory is instantaneously removed from $\mathcal{S}$. Since* *a continuous trajectory starting outside of $\mathcal{S}$ and intersecting the interior of $\mathcal{S}$ must first intersect the boundary of $\mathcal{S}$, it follows that no trajectory can reach the interior of $\mathcal{S}$.*

**Remark II.3.** *It follows from A1-A3 and Remark 1.2 that $\partial\mathcal{S} \cup \mathcal{S}$ is closed and hence the resetting times $t_k$ are well defined and distinct.*

**Remark II.4.** *Since the resetting times are well defined and distinct, and since the solutions to (II.1) exist and are unique, it follows that the solutions of the singularly impulsive dynamical system (II.1), (II.2) also exist and are unique over a forward time interval.*

In Haddad, Chellaboina and Kablar (2001a), the resetting set $\mathcal{S}$ is defined in terms of a countable number of functions $n_k : \mathbb{R}^n \to (0, \infty)$, and is given by

$$\mathcal{S} = \cup_k \{(n_k(x), x, u_{\mathrm{c}}(n_k(x)) : x \in \mathbb{R}^n\}. \qquad \text{(II.5)}$$

The analysis of singularly impulsive dynamical systems with time delay and with a resetting set of the form (II.5) can be quite involved. In particular, such systems exhibit Zenoness, beating, as well as confluence phenomena wherein solutions exhibit infinitely many transitions in a finite times, and coincide after a given point of time, Haddad, Chellaboina and Kablar (2001a). In this paper we assume that existence and uniqueness properties of a given singularly impulsive dynamical system with time delay are satisfied in forward time. Furthermore, since singularly impulsive dynamical systems of the form (II.1)-(II.4) involve impulses at variable times they are time-varying systems.

Here we will consider singularly impulsive dynamical systems involving two distinct forms of the resetting set $\mathcal{S}$. In the first case, the resetting set is defined by a prescribed sequence of times which are independent of state $x$. These equations are thus called *time-dependent singularly impulsive dynamical systems with time delay*. In the second case, the resetting set is defined by a region in the state space that is independent of time. These equations are called *state-dependent singularly impulsive dynamical systems with time delay*.

### A. Time-Dependent Singularly Impulsive Dynamical Systems with Time Delay

Time-dependent singularly impulsive dynamical systems with time delay can be written as (II.1)–(II.4) with $\mathcal{S}$ defined as

$$\mathcal{S} = n \times \mathbb{R}^n \times \mathcal{U}_{\mathrm{c}}, \qquad \text{(II.6)}$$

where

$$n = t_1, t_2, \ldots \qquad \text{(II.7)}$$

and $0 < t_1 < t_2 < \ldots$ are prescribed resetting times. When an infinite number of resetting times are used and $t_k \to \infty$ as $k \to \infty$, then $\mathcal{S}$ is closed. Now (II.1)–(II.4) can be rewritten in the form of the *time-dependent singularly impulsive dynamical system with time delay*

$$E_{\mathrm{c}}\dot{x}(t) = f_{\mathrm{c}}(x(t,\tau)) + G_{\mathrm{c}}(x(t,\tau))u_{\mathrm{c}}(t),\ t \neq t_k, \qquad \text{(II.8)}$$
$$E_{\mathrm{d}}\triangle x(t) = f_{\mathrm{d}}(x(t,\tau)_{+}G_{\mathrm{d}}(x(t,\tau))u_{\mathrm{d}}(t),\ t = t_k, \qquad \text{(II.9)}$$
$$y_c(t) = h_{\mathrm{c}}(x(t,\tau)) + J_{\mathrm{c}}(x(t,\tau))u_{\mathrm{c}}(t),\ t \neq t_k, \qquad \text{(II.10)}$$
$$y_d(t) = h_{\mathrm{d}}(x(t,\tau)) + J_{\mathrm{d}}(x(t,\tau))u_{\mathrm{d}}(t),\ t = t_k. \qquad \text{(II.11)}$$

Since $0 \notin \tau$ and $t_k < t_{k+1}$, $\tau > 0$, it follows that the assumptions A1–A3 are satisfied. Since time-dependent singularly impulsive dynamical systems with time delay involve impulses at a fixed sequence of times, they are time-varying systems.

**Remark II.5.** *The time-dependent singularly impulsive dynamical system with time delay (II.8)–(II.11), with $E_{\mathrm{c}} = I$ and $E_{\mathrm{d}} = I$ includes as a special case the impulsive control problem addressed in the literature wherein at least one of the state variables of the continuous-time plant can be changed instantaneously to any given value given by an impulsive control at a set of control instants $\tau$, Haddad, Chellaboina and Kablar (2001a).*

### B. State-Dependent Singularly Impulsive Dynamical Systems with Time Delay

State-dependent singularly impulsive dynamical systems with time delay can be written as (II.1)–(II.4) with $\mathcal{S}$ defined as

$$\mathcal{S} = [0, \infty) \times \mathcal{Z}, \qquad \text{(II.12)}$$

where $\mathcal{Z} = \mathcal{Z}_x \times \mathcal{U}_{\mathrm{c}}$ and $\mathcal{Z}_x \subset \mathbb{R}^n$. Therefore, (II.1)–(II.4) can be rewritten in the form of the *state-dependent singularly impulsive dynamical system with time delay*

$$E_{\mathrm{c}}\dot{x}(t) = f_{\mathrm{c}}(x(t,\tau)) + G_{\mathrm{c}}(x(t,\tau))u_{\mathrm{c}}(t),$$
$$(x(t,\tau), u_{\mathrm{c}}(t)) \notin \mathcal{Z}, \qquad \text{(II.13)}$$
$$E_{\mathrm{d}}\triangle x(t) = f_{\mathrm{d}}(x(t,\tau)) + G_{\mathrm{d}}(x(t,\tau))u_{\mathrm{d}}(t),$$
$$(x(t,\tau), u_{\mathrm{c}}(t)) \in \mathcal{Z}, \qquad \text{(II.14)}$$
$$y_{\mathrm{c}}(t) = h_{\mathrm{c}}(x(t,\tau)) + J_{\mathrm{c}}(x(t,\tau))u_{\mathrm{c}}(t),$$
$$(x(t,\tau), u_{\mathrm{c}}(t)) \notin \mathcal{Z}, \qquad \text{(II.15)}$$
$$y_d(t) = h_{\mathrm{d}}(x(t,\tau)) + J_{\mathrm{d}}(x(t,\tau))u_{\mathrm{d}}(t),$$
$$(x(t,\tau), u_{\mathrm{c}}(t)) \in \mathcal{Z}. \qquad \text{(II.16)}$$

We assume that $(x_0, u_{\mathrm{c}0}) \notin \mathcal{Z}$, $\tau > 0$, $(0, 0) \notin \mathcal{Z}$, and that the resetting action removes the pair $(x, u_{\mathrm{c}})$ from the set $\mathcal{Z}$; that is, if $(x, u_{\mathrm{c}}) \in \mathcal{Z}$ then $(E_{\mathrm{d}}x + f_{\mathrm{d}}(x) + G_{\mathrm{d}}(x)u_{\mathrm{d}}, u_{\mathrm{c}}) \notin \mathcal{Z}$, $u_{\mathrm{d}} \in \mathcal{U}_{\mathrm{d}}$. In addition, we assume that if at time $t$ the trajectory $(x(t,\tau), u_{\mathrm{c}}(t)) \in \bar{\mathcal{Z}} \backslash \mathcal{Z}$, then there exists $\epsilon > 0$ such that for $0 < \delta < \epsilon$, $(x(t + \tau + \delta), u_{\mathrm{c}}(t + \delta)) \notin \mathcal{Z}$.

These assumptions represent the specialization of A1–A3 for the particular resetting set (II.12). It follows from these assumptions that for a particular initial condition, the resetting times $\tau_k(x_0)$ are distinct and well defined. Since the resetting set $\mathcal{Z}$ is a subset of the state space and is independent of time, state-dependent singularly impulsive dynamical systems with time delay are time-invariant systems. Finally, in the case where $\mathcal{S} \equiv [0, \infty) \times \mathbb{R}^n \times \mathcal{Z}_{u_{\mathrm{c}}}$, where $\mathcal{Z}_{u_{\mathrm{c}}} \subset \mathcal{U}_{\mathrm{c}}$ we refer to (II.13)–(II.16) as an input-dependent singularly impulsive dynamical system with time delay. Both these cases represent a generalization to the impulsive control problem considered in the literature.

## III. Lyapunov and Asymptotic Stability of Singularly Impulsive Dynamical Systems with Time Delay

In this section we present Lyapunov and asymptotic stability results of singularly impulsive dynamical systems with time delay.

**Theorem III.1.** *Suppose there exists a continuously differentiable function $V : \mathcal{D} \to [0, \infty)$ satisfying $V(0) = 0$, $V(E_{\mathrm{c/d}}x) \geq 0$, $x \neq 0$, and*

$$V'(E_{\mathrm{c}}x)f_{\mathrm{c}}(x) \leq 0, \qquad x \in \mathcal{D}, \tag{III.17}$$

$$V(E_{\mathrm{d}}x + f_{\mathrm{d}}(x) \leq V(x), \qquad x \in \mathcal{D}. \tag{III.18}$$

*Then the zero solution $x(t,\tau) \equiv 0$ of the undisturbed $((u_{\mathrm{c}}(t), u_{\mathrm{d}}(t_k)) \equiv (0,0))$ time-dependent singularly impulsive dynamical system with time delay (II.8),(II.9) is Lyapunov stable. Furthermore, if the inequality (III.17) is strict for all $x \neq 0$, then the zero solution $x(t,\tau) \equiv 0$ of the undisturbed $((u_{\mathrm{c}}(t), u_{\mathrm{d}}(t_k)) \equiv (0,0))$ time-dependent singularly impulsive dynamical system with time delay (II.8), (II.9) is asymptotically stable. If, in addition, $\mathcal{D} = \mathbb{R}^n$ and*

$$V(E_{\mathrm{c/d}}x) \to \infty \text{ as } \|x\| \to \infty, \tag{III.19}$$

*then the zero solution $x(t,\tau) \equiv 0$ of the undisturbed $((u_{\mathrm{c}}(t), u_{\mathrm{d}}(t_k)) \equiv (0,0))$ time-dependent singularly impulsive dynamical system with time delay (II.8), (II.9) is globally asymptotically stable, Haddad, Chellaboina, and Kablar (2001), Kablar (2003b).*

*Proof:* Prior to the first resetting time, we can determine the value of $V(x(t,\tau))$ as

$$V(E_{\mathrm{c}}x(t,\tau)) \;=\; V(E_{\mathrm{c}}x(0)) + \int_0^t V'(x(E_{\mathrm{c}}))f_{\mathrm{c}}(x(s,\tau)\mathrm{d}s, \qquad t \in [0, t_1]. \tag{III.20}$$

Between consecutive resetting times $t_k$ and $t_{k+1}$, we can determine the value of $V(x(t,\tau))$ as its initial value plus the integral of its rate of change along the trajectory $x(t,\tau)$, that is,

$$\begin{aligned} V(E_{\mathrm{c/d}}x(t,\tau) \;&=\; V(E_{\mathrm{d}}x(t_k) + f_{\mathrm{d}}(x(t_k)) \\ &\quad + \int_{t_k}^t V'(x(E_{\mathrm{c}}))f_{\mathrm{c}}(x(s,\tau))\mathrm{d}s, \\ &\qquad t \in (t_k, t_{k+1}], \end{aligned} \tag{III.21}$$

for $k = 1, 2, \ldots$. Adding and subtracting $V(x(E_{\mathrm{d}}t_k))$ to and from the right hand side of the (III.21) yields

$$\begin{aligned} V(E_{\mathrm{c/d}}x(t,\tau)) = {} & V(E_{\mathrm{c}}x(t_k)) + [V(E_{\mathrm{d}}x(t_k) \\ & + f_{\mathrm{d}}(x(t_k)) - V(E_{\mathrm{d}}x(t_k))] \\ & + \int_{t_k}^t V'(E_{\mathrm{c}}x(s,\tau))f_{\mathrm{c}}(x(s,\tau))\mathrm{d}s, \quad t \in (t_k, t_{k+1}], \end{aligned} \tag{III.22}$$

and in particular at time $t_{k+1}$,

$$\begin{aligned} V(E_{\mathrm{d}}x(t_{k+1})) = {} & V(E_{\mathrm{d}}x(t_k)) + [V(E_{\mathrm{d}}x(t_k) \\ & + f_{\mathrm{d}}(x(t_k))) - V(E_{\mathrm{d}}x(t_k))] \\ & + \int_{t_k}^{t_{k+1}} V'(x(s,\tau))f_{\mathrm{c}}(x(s,\tau))\mathrm{d}s. \end{aligned} \tag{III.23}$$

By recursively substituting (III.23) into (III.22) and ultimately into (III.20), we obtain

$$V(E_{\mathrm{c}}x(t,\tau)) = V(E_{\mathrm{c}}x(0)) + \int_0^t V'(E_{\mathrm{c}}x(s,\tau))f_{\mathrm{c}}(x(s,\tau))\mathrm{d}s$$

$$+ \sum_{i=1}^{k}[V(E_{\mathrm{d}}x(t_i) + f_{\mathrm{d}}(x(t_i))) - V(E_{\mathrm{d}}x(t_i))]]. \tag{III.24}$$

If we allow $t_0 = 0$, and $\sum_{i=1}^{0} = 0$, then (III.24) is valid for $k \in \mathcal{N}$. From (III.24) and (III.18) we obtain

$$\begin{aligned} & V(E_{\mathrm{c}}x(t,\tau)) \;\leq \\ & V(E_{\mathrm{c}}x(0)) + \int_0^t V'(E_{\mathrm{c}}x(s,\tau))f_{\mathrm{c}}(x(s,\tau))\mathrm{d}s, \\ & \qquad t \geq 0. \end{aligned} \tag{III.25}$$

Furthermore, it follows from (III.17) that

$$V(E_{\mathrm{c}}x(t,\tau)) \leq V(E_{\mathrm{c}}x(0)), \qquad t \geq 0, \tag{III.26}$$

so that Lyapunov stability follows from standard arguments.

Next, it follows from (III.18) and (III.24) that

$$V(E_{\mathrm{c}}x(t,\tau)) - V(E_{\mathrm{c}}x(s,\tau)) \;\leq\; \int_s^t V'(x(E_{\mathrm{c}}s,\tau))f_{\mathrm{c}}(x(s,\tau))\mathrm{d}s, \qquad t > s, \tag{III.27}$$

and, assuming strict inequality in (III.17), we obtain

$$V(E_{\mathrm{c}}x(t,\tau)) < V(E_{\mathrm{c}}x(s,\tau)), \qquad t > s, \tag{III.28}$$

provided $x(s,\tau) \neq 0$. Asymptotic stability, and, with (III.19), global asymptotic stability, then follow from standard arguments. ■

**Remark III.1.** *If in Theorem III.1 the inequality (III.18) is strict for all $x \neq 0$ as opposed to the inequality (III.17), and an infinite number of resetting times are used, that is, the set $\tau = \{t_1, t_2, \ldots\}$ is infinitely countable, then the zero solution $x(t,\tau) \equiv 0$ of the undisturbed time-dependent singularly impulsive dynamical system with time delay (II.8), (II.9) is also asymptotically stable. A similar remark holds for Theorem 2.2.2.*

**Remark III.2.** *In the proof of Theorem III.1, we note that assuming strict inequality in (III.17), the inequality (III.28) is obtained* provided $x(s,\tau) \neq 0$. *This proviso is necessary since it may be possible to reset the states to the origin, in which case $x(s,\tau) = 0$ for a finite value of $s$. In this case, for $t > s$, we have $V(E_{\mathrm{c}}x(t,\tau)) = V(E_{\mathrm{c}}x(s,\tau)) = V(0) = 0$. This situation does not present a problem, however, since reaching the origin in finite time is a stronger condition than reaching the origin as $t \to \infty$.*

**Remark III.3.** *If, additionally, in Theorem III.1 there exist scalars $\alpha, \beta, \epsilon > 0$, and $p \geq 1$, such that $\alpha\|x\|^p \leq V(E_{\rm c}x) \leq \beta\|x\|^p$, $x \in \mathcal{D}$, and (III.17) is replaced by $V'(E_{\rm c}x)f_{\rm c}(x) \leq -\epsilon V(E_{\rm c}x)$, $x \in \mathcal{D}$, then the zero solution $x(t,\tau) \equiv 0$ of the undisturbed $((u_{\rm c}(t), u_{\rm d}(t_k)) \equiv (0,0))$ time-dependent singularly impulsive dynamical system with time delay (II.8), (II.9) is exponentially stable. A similar remark holds for Theorem 2.2.2.*

**Remark III.4.** *Theorem III.1 presents sufficient conditions for time-dependent singularly impulsive dynamical systems with time delay in terms of Lyapunov functions that do not depend explicitly on time. Since time-dependent singularly impulsive dynamical systems are time-varying, Lyapunov functions that explicitly depend on time can also be considered. However, in this case the conditions on the Lyapunov functions required to guarantee stability are significantly harder to verify. For further details see Bainov and Simeonov (1989), Samoilenko and Perestyuk (1995), Ye, Michael, and Hou (1998).*

Next, we state a stability theorem for nonlinear state-dependent singularly impulsive dynamical systems with time delay.

**Theorem III.2.** *Suppose there exists a continuously differentiable function $V : \mathcal{D} \to [0,\infty)$ satisfying $V(0) = 0$, $V(E_{\rm c}x) \geq 0$, $x \neq 0$, and*

$$V'(E_{\rm c}x)f_{\rm c}(x) \leq 0, \qquad x \notin \mathcal{Z}_x, \qquad \text{(III.29)}$$

$$V(E_{\rm d}x + f_{\rm d}(x)) \leq V(E_{\rm c}x), \qquad x \in \mathcal{Z}_x. \qquad \text{(III.30)}$$

*Then the zero solution $x(t,\tau) \equiv 0$ of the undisturbed $((u_{\rm c}(t), u_{\rm d}(t_k)) \equiv (0,0))$ state-dependent singularly impulsive dynamical system with time delay (II.13), (II.14) is Lyapunov stable. Furthermore, if the inequality (III.29) is strict for all $x \neq 0$, then the zero solution $x(t,\tau) \equiv 0$ of the undisturbed $((u_{\rm c}(t), u_{\rm d}(t_k)) \equiv (0,0)$ state-dependent singularly impulsive dynamical system with time delay (II.13), (II.14) is asymptotically stable. If, in addition, $\mathcal{D} = \mathbb{R}^n$ and (III.19) is satisfied, then the zero solution $x(t,\tau) \equiv 0$ of the undisturbed $((u_{\rm c}(t), u_{\rm d}(t)k)) \equiv (0,0))$ state-dependent singularly impulsive dynamical system with time delay (II.13), (II.14) is globally asymptotically stable, Haddad, Chellaboina, and Kablar (2001), Kablar (2003b).*

*Proof:* For $\mathcal{S} = [0,\infty) \times \mathcal{Z}_x$ it follows from Assumptions A1–A3 that the resetting times $n_k(x_0)$ are well defined and distinct for every trajectory of (II.13), (II.14) with $(u_{\rm c}(t), u_{\rm d}(t_k)) \equiv (0,0)$. Now, the proof follows as in the proof of Theorem III.1 with $t_k$ replaced by $n_k(x_0)$. ■

**Remark III.5.** *To examine the stability of linear state-dependent singularly impulsive dynamical systems with time delay set $f_{\rm c}(x) = A_{\rm c}x$, and $f_{\rm d}(x) = (A_{\rm d} - E_{\rm d})x$ in Theorem III.2. Considering the quadratic Lyapunov function candidate $V(E_{\rm c/d}x) = x^{\rm T}E_{\rm c/d}^{\rm T}PE_{\rm c/d}x$, for the argument $E_{\rm c}x$ and $E_{\rm d}x$, respectively where $P > 0$, it follows from Theorem III.2 that the conditions*

$$x^{\rm T}(A_{\rm c}^{\rm T}PE_{\rm c} + E_{\rm c}^{\rm T}PA_{\rm c})x < 0, \qquad x \notin \mathcal{Z}_x, \qquad \text{(III.31)}$$

$$x^{\rm T}(A_{\rm d}^{\rm T}PA_{\rm d} - E_{\rm d}^{\rm T}PE_{\rm d})x \leq 0, \qquad x \in \mathcal{Z}_x, \qquad \text{(III.32)}$$

*establish asymptotic stability for linear state-dependent singularly impulsive dynamical systems with time delay. These conditions are implied by $P > 0$, $A_{\rm c}^{\rm T}PE_{\rm c} + E_{\rm c}^{\rm T}PA_{\rm c} < 0$, and $A_{\rm d}^{\rm T}PA_{\rm d} - E_{\rm d}^{\rm T}PE_{\rm d} \leq 0$ which can be solved using Linear Matrix Inequality (LMI) feasibility problem Boyd et al. (1994). See also Haddad, Chellaboina, and Kablar (2001a).*

## IV. Conclusion

In this paper we presented new class of singularly impulsive or generalized impulsive dynamical systems with delay. We gave assupmtions needed for the model and basic division of singularly impulsive dynamical systems into twio classes: time dependenet and state dependent. Next, we developed Lyapunov and asymptotic stability results.

## V. Future Work

It is left to develop invariant set theorem for singularly impulsive dynamical systems. Next, further work will concentrate to specializing this results and developing to time-delay systems. The last is motivated by recognized need in biological applications.

On the other hand finite-time and practical stability results will be developed for the class of impulsive and singularly impulsive dynamical systems with delay.

## VI. Acknowledgment

The author is grateful to all that were supportive and creative in achieving these results.

*Abstract*— **In this work, a model-based fault detection and isolation (FDI) is developed for proton exchange membrane (PEM) fuel cell (FC) stack that is under feed-forward plus feedback control. The fault detection is achieved using an independent radial basis function (RBF) network model, whilst the fault isolation is based on the RBF classification. The novelty is that the RBF model of independent mode is used to predict the future outputs of the FC stack and a RBF classifier is used to classify five types of fault introduced to the PEMFC systems. To validate the method, a benchmark model developed by Michigan University is used in the simulation to analyze the effectiveness of the method for actuator, component and three sensor faults. The FDI results corresponding to those scenarios show that the simulated different types of fault are successfully detected and isolated.**

***Keywords-Proton exchange membrane fuel cell; feed-forward; feedback; fault detection; fault isolation; radial basis function; independent model***

## I. INTRODUCTION

Process faults, if undetected, have a serious impact on process economy, product quality, safety, pollution level and productivity. In order to detect, diagnose and correct these abnormal process behaviors, efficient and advanced automated diagnostic systems are of great importance to modern industries [1]. Once a fault has been detected and its evolution is monitored, the severity of that fault can be evaluated and a decision can be made on the course of action to take. Monitoring creates the opportunity to strategically plan and schedule outrages and to manage equipment utilization and availability [2]. Fault detection, isolation and reconfiguration (FDIR) is an important and challenging task in many engineering applications and continues to be an active area of research in the control environment [3]. In some cases, if a fault can be quickly detected and identified, appropriate reconfiguration control actions may be taken. FDIR is a control methodology which ensures continual safe and acceptable operation of the system when a fault occurs through fault detection and isolation (FDI). Many devices depend on automatic control for satisfactory operation, and while assuring stability and performance with all components functioning properly. If the control system's structure or parameter can be altered in response to system failure, it is said to be reconfigurable [4].

There are a large number of publications on the fuel cell (FC) studies, but studies on FDI are still a few. Model-based FDI methods for PEMFC become more and more important because it involved the comparison between the observed behavior of the process with a reference model. Model-based approach gives the insight analysis of the subsystem interactions and also provides guidelines during the conduction of the experiment. The system behavior can been analyzed in depth understanding and later this information can be used for future design and development. For fault detection problem, the most effective way is by using the model-based approach based on a residual generation. Here, the difference between the actual process and estimated output of the process is used as a residual vector. In [5] presented and tested a model-based fault diagnosis methodology based on the relative residual fault sensitivity. In this method, it checks the consistency of observed behavior and then isolate the component that is in fault in different sensitivities. While, a robust fault detection based on the use of LPV observer using output zonotopes was proposed by [6]. Here, fault isolation is based on set of structured residuals that are analyzed using a relative fault sensitivity approach.

Neural networks have been proposed as an alternative method for fault diagnosis by many authors especially to tackle the nonlinear behavior. Reference [7] used a Bayesian network as an early alert to diagnose faults in the air reaction fan, faults in the cooling system, growth of the fuel crossover and internal loss current and faults in the hydrogen feed line. Alternatively, to improve reliability and durability of PEMFC systems, [8] presents a flooding diagnosis based on black-box model of elman neural network (ENN). Here, ENN is used to do a comparison between measured and calculated pressure drops. The model-based on ENN is trained with data recorded in flooding-free condition and the difference between calculated and experimental pressure drop is used as the residual. Also concern about this problem in FC, [9] presents an electric equivalent model for FC system diagnosis emphasis on FC flooding detection induced by temperature. In this paper, to tackle the efficiency of the overall PEMFC systems, a model-based FDI based on residual generation is used to implement the fault detection whilst for fault isolation a RBF networks is

978-1-4673-1560-9/12/$31.00 ©2012 IEEE

used as a classifier. Therefore, to make the FDI monitoring system more efficient and robust to the faults in the PEMFC systems, an independent RBF network is used for fault identification, detection and isolation. The aim of this work is to develop a FDI scheme under closed-loop system for PEMFC using an independent RBF network model which can detect five types of faults in the FC systems accordingly but also can also isolate them accurately.

## II. PEMFC DYNAMICS

The proton exchange membrane fuel cell (PEMFC) systems offer high efficiency and low emissions and has been become popular as an alternate power source for various application such as transportation, telecommunication, portable utilities, stationary and power generation. A typical PEMFC system normally consist of four subsystems, which include the reactant flow subsystem, the heat and temperature subsystem, the water management subsystem and the power management subsystem. The PEMFC stack is made up of 381 cells with an active area of 280cm$^2$ and the stack operating temperature is at 80°C developed by University Michigan is used as a test bench.

### A. Compressor Model

The flow and temperature out of the compressor ($W_{cp}$ and $T_{cp}$) depend on the compressor rotational speed $\omega_{cp}$. A lumped rotational model is used to represent the dynamic behaviour of the compressor [10]:

$$J_{cp}\frac{d\omega_{cp}}{dt} = \tau_{cm} - \tau_{cp} \tag{1}$$

where $\tau_{cm}(v_{cm},\omega_{cp})$ is the compressor motor (CM) torque and $\tau_{cp}$ is the load torque. The compressor motor torque is calculated using a static motor equation:

$$\tau_{cm} = \eta_{cm}\frac{k_t}{R_{cm}}\left(V_{cm} - k_v\omega_{cp}\right) \tag{2}$$

where $k_t$, $R_{cm}$ and $k_v$ are motor constants and $\eta_{cm}$ is the motor mechanical efficiency. The torque required to drive the compressor is calculated using the thermodynamic equation:

$$\tau_{cp} = \frac{c_p T_{atm}}{\omega_{cp}\eta_{cp}}\left[\left(\frac{p_{sm}}{p_{atm}}\right)^{(\gamma-1)/\gamma} - 1\right]W_{cp} \tag{3}$$

where $\gamma$ is the ratio of the specific heats of air (=1.4), $c_p$ is the constant pressure specific heat capacity of air (=1004 J.kg$^{-1}$.K$^{-1}$), $\eta_{cp}$ is the motor compressor efficiency, $p_{sm}$ is the pressure inside the supply manifold and $p_{atm}$ and $T_{atm}$ are the atmospheric pressure and temperature, respectively.

### B. Supply Manifold Model

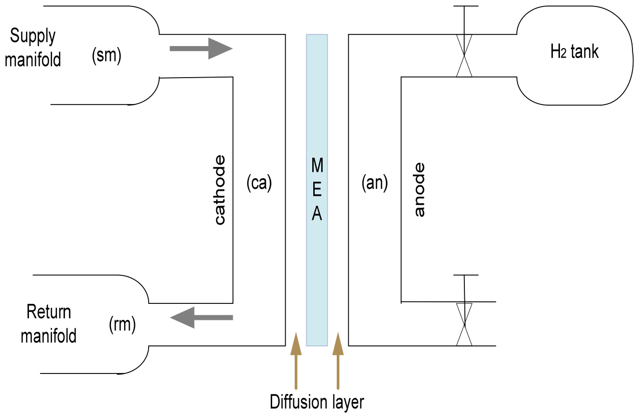

Figure 1. The fuel cell reactant supply system

The cathode supply manifold (sm) includes pipe and stack manifold volumes between the compressor and the fuel cells as shown in Fig. 1. The supply manifold pressure, *psm*, is governed by mass continuity and energy conservation equations [11]:

$$\frac{dm_{sm}}{dt} = W_{cp} - W_{sm,out} \tag{4}$$

$$\frac{dp_{sm}}{dt} = \frac{\gamma R_a}{V_{sm}}\left(W_{cp}T_{cp} - W_{sm,out}T_{sm}\right) \tag{5}$$

where R is the universal gas constant and $M_a^{atm}$ is the molar mass atmospheric air at $\Phi_{atm}$, $V_{sm}$ is the manifold volume and $T_{sm} = \frac{p_{sm}v_{sm}M_a^{atm}}{Rm_{sm}}$ is the supply manifold gas temperature.

## III. FDI METHOD WITH INDEPENDENT RBF MODEL

The basic structure of an independent radial basis function (RBF) model for PEMFC dynamic systems proposed in this work can be referred to Fig. 2. Here, two inputs and three outputs of the process with their delayed values form the 8 inputs of the RBF model, while the three process outputs are the model outputs. The chosen input output orders are according to the training experience and checking the process dynamics. The model prediction errors are generated for residual generation.

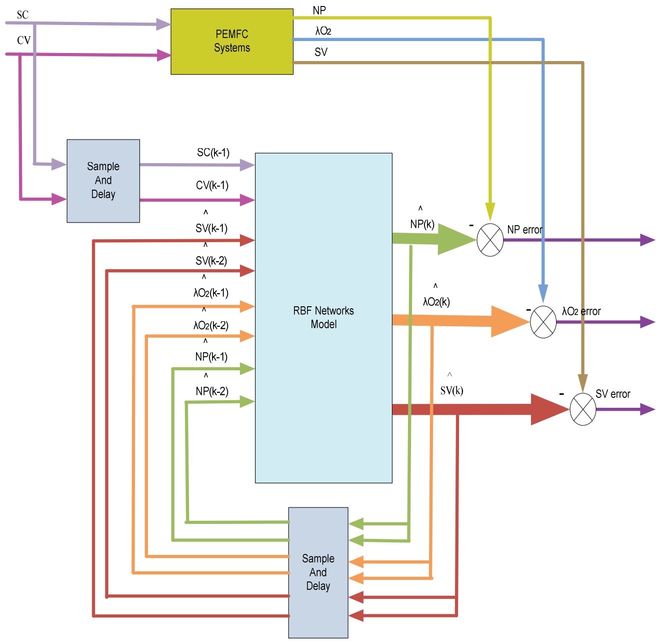

Figure 2. The structure of an independent RBF network

## IV. CONTROLLER DESIGN

For air supply in the PEMFC systems, the required air flow is indicated by the desired oxygen excess ratio, $\lambda O_2$ = 2. Generating rapid increase in air flow, however, requires a large amount of power drawn by the compressor motor and a affecting the system net power [12]. The combination of feed-forward and feedback control design objective is to manipulate the compressor motor input voltage, $V_{cm}$, in order to maintain $\lambda O_2 = 2$.

### A. Feed-forward Controller

A feed-forward control is used to control $V_{cm}$ based on the current drawn from the FC stack. In this work, look-up table act as feed-forward control as presented in Table I with respect to the signal range of stack current ranging from 100 to 300 amperes. To design the feed-forward controller, the stack current signal is adjust at the value illustrated in Table I and fed to the FC stack while tuning the $V_{cm}$ until $\lambda O_2 = 2$.

TABLE I. THE DESIGN OF FEED-FORWARD CONTROLLER

| **Stack Current (Ampere)** | **Compressor Voltage (Volt)** | **Gain = Output / Input** | **Stack Current (Ampere)** | **Compressor Voltage (Volt)** | **Gain = Output / Input** |
|---|---|---|---|---|---|

### B. Proportional-Integral-Derivative Controller

A proportional-integral-derivative (PID) controller is used to reduce the effects the disturbances that can be measured and also to improve the response to reference signals. The PID controller equation is given by:

$$PID_{controller} = 200\left(1 + \frac{1}{0.6153\,s} + 0.05\,s\right) \qquad (6)$$

Fig. 3 shows the overall control systems of feed-forward and a closed-loop control implemented in this work. In the diagram, the stack current acts as a disturbance to the PEMFC systems with a reference input set at 2 ($\lambda O_2 = 2$). The output of $\lambda O_2$ need to maintain in order to avoid oxygen starvation from happening.

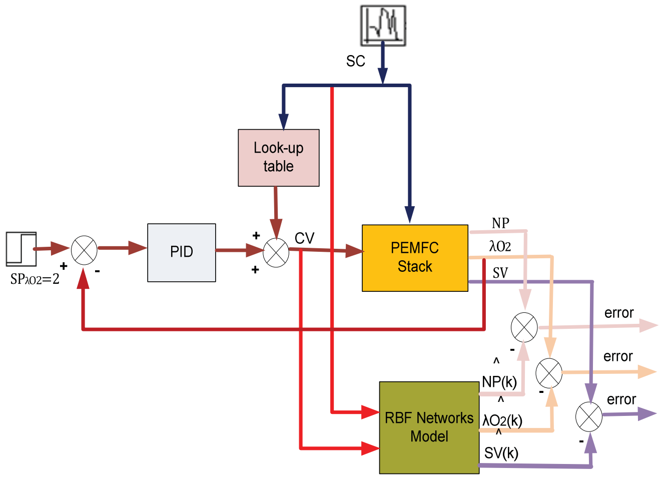

Figure 3. The overall system of FDI using feed-forward and feed-back controller

## V. SIMULATING FAULTS

In this study, five faults are introduced to a known test bench PEMFC based on the model developed in Michigan University. First one is an actuator fault, which is simulated by superimposing a -10% change of the compressor motor voltage measurement. The second is the air leak in the supply manifold which is a typical component fault. The third to fifth are three sensor faults for the three outputs, which are simulated by 10% deviation superimposed to the net power, $\lambda O_2$ and stack voltage output measurements. The PEMFC simulator was modified to include five possible fault scenarios which may occur during the normal operation of PEMFC systems. Fig. 4 shows the five faults introduced to the overall PEMFC systems.

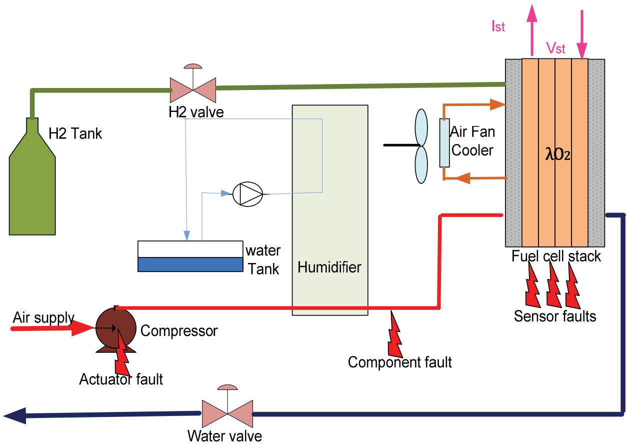

Figure 4. The schematic of PEMFC systems with five types of faults

*1) Actuator fault:* Mostly centrifugal compressor is used in FCs are susceptible to surge and choke that limit the efficiency and performance of the compressor. The compressor voltage will be changed if the compressor experience surge and choke and affected the air flow in the supply manifold. The compressor motor performance is reduced by -10% of the total compressor motor voltage from the sample intervals, k=2500-2550 to reflect the scenario of the fault which happens at the actuator part.

2) *Component fault:* Air leakage in the supply manifold makes the pressure in the cathode decrease. Therefore to collect the FC stack data subjected to the air leak fault, equation (5) is modified to:

$$\frac{dp_{sm}}{dt} = \frac{\gamma R_a}{V_{sm}}\left(W_{cp}T_{cp} - W_{sm,out}T_{sm} - \Delta l\right) \tag{7}$$

where Δl is used to simulate the leakage from the air manifold, which is subtracted to increase the air outflow from the supply manifold. Δl=0 represents that there is no air leakage in the supply manifold. The air leakage is simulated by -10% change of the pressure inside the supply manifold. The fault occurs at the sample intervals, *k* = 2000-2050.

3) *Sensor faults:* Net power, $\lambda O_2$ and stack voltage sensors are considered experiencing over-reading faults. The faulty sensor data used was the data from the collected data set, superimposed with a 10% change of the measured net power over the sample interval, k = 500-550, a 10% change of the measured $\lambda O_2$ over the sample intervals, k = 1000-1050 and a 10% change of the measured stack voltage over the sample intervals, k = 1500-1550.

## VI. FAULT DETECTION AND ISOLATION

### *A. Fault Detection*

Though the filtered squared model prediction error for each output could be used as fault detection signal, a residual signal is generated by combine these prediction errors, so that the sensitivity of the residual to each fault can be significantly enhanced, and consequently the false alarm rate would be reduced. The residual in this work is defined as in (8).

$$re = \sqrt{e_{NP}^2 + e_{\lambda O2}^2 + e_{SV}^2} \tag{8}$$

where $e_{NP}$ is the filtered modeling error of net power, $e_{\lambda O2}$ is the filtered modeling error of $\lambda O_2$ and $e_{SV}$ is the filtered modeling error of stack voltage. The signal with faults is clearly been identified and less influences by a noise signal.

### *B. Fault Isolation*

RBF classifier is a nonlinear static network. The network is trained with a set of data collected under each of the five faults and no-fault condition. The five outputs are arranged in this way: The target for any one output is arranged to be "1" when the corresponding single fault occurs, and to be "0" when this single fault does not occur. In this study, 3000 samples of data were collected with the first fault occurring during *k* = 500~550, the second fault occurring during *k* = 1000-1050, and etc. Then, the generated filtered and squared model prediction error vector from the fault detection part was used as the input data of the RBF classifier. Correspondingly, the target matrix $X_0$ has 3000 rows and 5 columns. The entries from the 500th row to the 550th row in the first column are "1", while the other entries are "0". The arrangement for the column 2 to 5 is done in the same way. This is shown as in Table II.

TABLE II. THE TARGET MATRIX IN TRAINING THE RBF CLASSIFIER

| **Rows** | **$X_0$** | | | | |
|---|---|---|---|---|---|
| 500~550 | [1 | 0 | 0 | 0 | 0] |
| 1000~1050 | [0 | 1 | 0 | 0 | 0] |
| 1500~1050 | [0 | 0 | 1 | 0 | 0] |
| 2000~2050 | [0 | 0 | 0 | 1 | 0] |
| 2500~2550 | [0 | 0 | 0 | 0 | 1] |

## VII. SIMULATION RESULTS

A random amplitude signals (RAS) of stack current used as disturbances to the PEMFC systems has been injected to the FC stack. At the same time, the constructed table described in the previous section act as a feed-forward control is the input to compressor motor. The RAS excitation signals of stack current are generated randomly to cover the whole range of frequencies and entire operating space of amplitude in the PEMFC systems.

Later, a data set with 3000 samples is acquired from the plant when the five faults are simulated to the plant as described in previous section. The simulation result of three PEMFC outputs and the corresponding five faults is shown in Fig. 5. It shows the squared filtered model prediction error for the three output variables. As can be seen, there are more than one faults occurred in these three outputs.

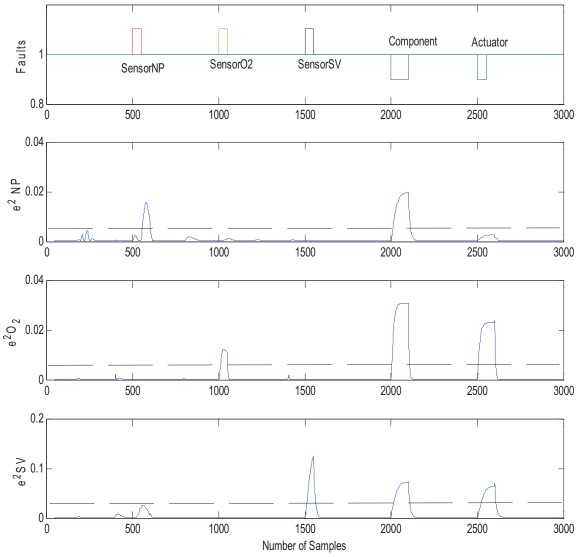

Figure 5. Filtered model predicted errors

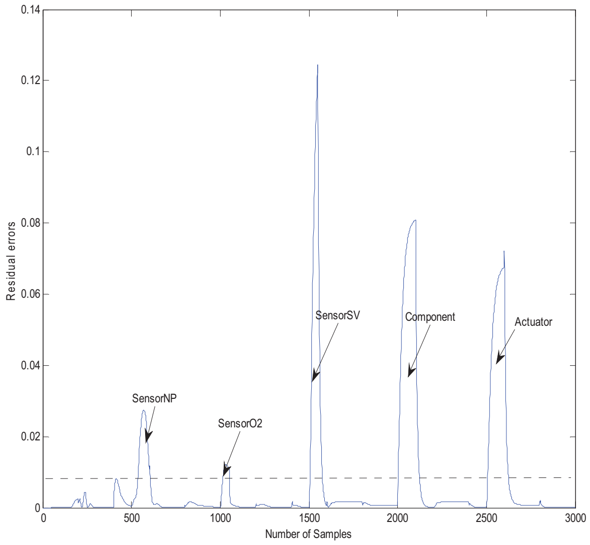

Figure 6. The fault classification of residual generator

In order to do fault classification, the residual generation as stated in equation (8) was applied. Here, the fault occurrence can clearly identified and detected with their respective threshold after the implementation. It is observed in Fig. 6 that all five faults of +10% for three sensors and -10% for component and actuator faults are clearly detected.

The target matrix in Table II was used in training of the RBF classifier. The centres and widths of the network were chosen using the K-means clustering algorithm and the p-nearest centre algorithm. The weights were trained with using the RLS algorithm with the following data, $\mu$= 0.99999, $w(0) = 1.0\times10^{-6}\times U_{(nh\times3)}$, $P(0)=1.0\times10^{8}\times I_{(nh)}$; where $I$ is an identity matrix and $U$ is an ones matrix. The RBF networks model only used the three rows of the PEMFC outputs matrix which contain the values of net power, $\lambda O_2$ and stack voltage. After training, a similar data set with also 3000 samples, with the same five faults simulated, was collected. These data was applied to the fault detection part and then to the isolation part with the trained RBF classifier. The five outputs of the classifier are displayed in Fig. 7.

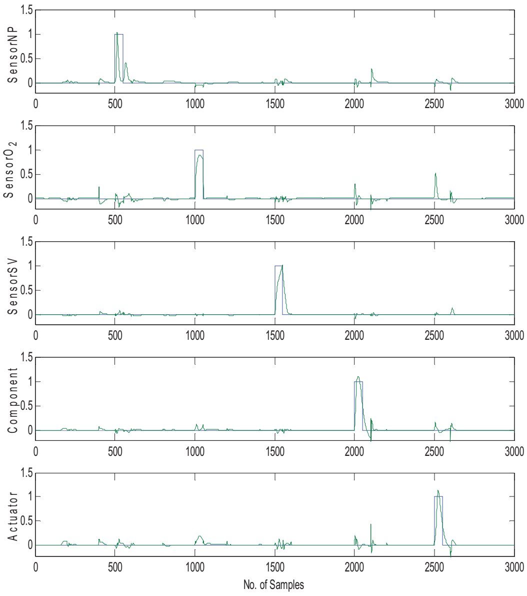

Figure 7. The fault isolation for five faults during training

From the fault isolation signals in Fig. 7 it is clearly observed that all considered five faults have been isolated. The RBF classifier successfully suppressed the corresponding output value for the no-fault-occurring period, while promoted the corresponding output value for the fault-occurring period. It is noticed in Fig. 7 that the fault isolation signals are very noisy and that would cause false alarm. Then, the RBF classifier outputs are filtered and the filtered signals are displayed in Fig. 8. It is obvious that the filtered fault isolation signals are much smoother and the robustness of the signal to modeling errors, interactions between variables and noise is greatly enhanced. It is important to isolate the malfunction devices in the systems for easy troubleshooting and maintenance purposes. By doing this step, the device can easily be replaced and any appropriate action can be taken quickly and therefore it can save time and increase productivity.

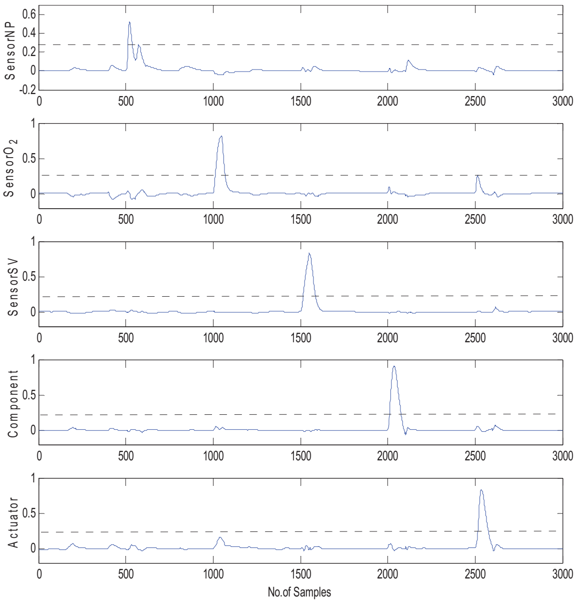

Figure 8. The location of five faults in the PEMFC systems

## VIII. CONCLUSIONS

A combination of feed-forward and feedback controller is designed to regulate the $\lambda O_2$ during the changes of stack current in the FC stack. FDI has been developed for the PEMFC under the closed-loop control. Five faults are simulated and diagnosed. The simulation results show that the new approach using the residual generation to do fault detection and the RBF classifier to apply fault isolation is successfully implemented. The 10% faults in the actuator, component and three sensors can be clearly detected and isolated. Here, the fault condition is considered occurred as a single fault at a time. But this result can be extended to the fault condition of multi-faults occurring simultaneously. The extension for fault detection part is straightforward, while for fault isolation needs more complex training of the fault classifier. The developed method has a big potential to be applied to real world dynamic systems. Also, the method is not limited to FC systems, and can be applied to other multivariable nonlinear dynamic systems with some modifications.

***Abstract*—The robust model-based predictive control (RMPC) formulation originally proposed in [1] ensures convergence of the state trajectory to the origin and satisfaction of operational constraints, provided that a given system of LMIs is feasible at the beginning of the control task. The largest domain of attraction of the origin under the resulting closed-loop control law can be defined as the set of all state values for which the LMIs are feasible. The present paper demonstrates that such a set is convex and symmetric about the origin, which allows the determination of extreme points through the solution of a modified version of the original RMPC optimization problem. An inner approximation of the largest domain of attraction can then be generated as the convex hull of these extreme points. The convexity and symmetry properties are also demonstrated for regions of guaranteed cost, defined as the set of initial states for which the resulting cost is upper-bounded by a given value. Inner approximations of such regions can also be obtained by solving a modified version of the RMPC optimization problem. For illustration, a numerical simulation model of an angular positioning system is employed, as in [1]. In this example, the proposed approximations were found to be in agreement with the feasibility and cost results obtained in a pointwise manner for a grid of initial conditions.**

***Index Terms*—Robust model predictive control, linear matrix inequalities, domain of attraction, convex optimization.**

## I. Introduction

The term Model-based Predictive Control (MPC) refers to a body of techniques that involve the solution of an optimal control problem within a receding horizon [2]. MPC has become widespread in several application areas, mainly due to the possibility of addressing operational constraints in an explicit manner [3]. Constraint satisfaction and closed-loop stability can be guaranteed by a proper formulation of the receding-horizon optimization problem. Usually, the adoption of target sets that are invariant under locally stabilizing control laws is employed for this purpose [4]. However, the design guarantees may be lost if the prediction model does not match the actual plant dynamics. Such a mismatch may arise due to modelling approximations (linearization and order reduction, for example), parameter uncertainties or variations in the plant behaviour due to faults or natural aging. This problem has motivated the development of robust MPC (RMPC) techniques.

Early formulations of RMPC involved the online solution of a min-max optimization problem, where the worst case value of the cost function was evaluated over a set of uncertain plants [5], [6], [7]. However, the computational cost of the resulting problem could become prohibitive for actual implementation. In this context, Kothare and collaborators [1] proposed an RMPC approach based on linear matrix inequalities (LMIs). By using the proposed approach, the optimization problem was cast into a semi-definite programming (SDP) form [8], which allowed the use of efficient numerical solvers to obtain the optimal control in polynomial time. Moreover, operational constraints could be easily introduced by augmenting the problem formulation with additional LMIs. This seminal work was later extended to encompass the use of output feedback [9], [10], [11], as well as the control of nonlinear systems [12] systems with uncertain time delay [13], [14], [15], and systems with asymmetric output constraints [16]. Modifications to the LMI formulation aimed at reducing conservatism have also been proposed [17], [18], [19], [20].

Within the framework developed in [1], the state trajectory is guaranteed to converge to the origin with satisfaction of the operational constraints, provided that the system of LMIs is feasible at the beginning of the control task. Therefore, the largest domain of attraction of the origin under the closed-loop control law can be defined as the set of all state values (i.e. initial conditions for the state trajectory) for which the LMIs are feasible. However, the analytical or numerical characterization of such a domain of attraction was not discussed in [1]. In fact, although the solution of the SDP problem for a given initial condition can be used to establish an asymptotically stable invariant ellipsoid [1], [21], such an ellipsoid is not necessarily the largest domain of attraction for the origin. It is possible to maximize the size of this invariant ellipsoid by using a determinant maximization procedure, as proposed in [12]. Yet, one may still argue that the largest domain of attraction is not necessarily of ellipsoidal shape.

The present paper establishes some properties of the largest domain of attraction $\mathcal{D}$ for the RMPC approach developed in [1]. More specifically, it is demonstrated that $\mathcal{D}$ is convex and symmetric about the origin. In view of such properties, extreme points of $\mathcal{D}$ can be found by solving a modified version of the original RMPC optimization problem. An inner approximation of $\mathcal{D}$ can then be generated as the convex hull of the extreme points thus obtained. The resulting approximation can be useful, for instance, to design schemes for the commutation between different RMPC controllers, as well as to choose an appropriate initial condition during the planning stage of a control manoeuvre.

It is worth noting that the initial feasibility of the RMPC optimization problem guarantees that the state trajectory will converge to the origin, but does not ensure that the performance will be acceptable. Therefore, it would also be of value to characterize a set $\mathcal{D}^{\bar{\gamma}}$ of initial conditions for which the resulting cost function value is smaller or equal to a given scalar $\bar{\gamma} > 0$. In this work, such a set will be termed "region of guaranteed cost". As an additional contribution of the present paper, the symmetry and convexity properties of $\mathcal{D}$ are also demonstrated for $\mathcal{D}^{\bar{\gamma}}$. Thus, an inner approximation of $\mathcal{D}^{\bar{\gamma}}$ can also be obtained by solving a modified version of the original RMPC optimization problem.

For illustration, a numerical simulation model of an angular positioning system is employed, as in [1]. The remaining of this paper is organized as follows. Section II describes the LMI-based RMPC formulation adopted in the present work. Section III demonstrates the symmetry and convexity properties of the largest domain of attraction $\mathcal{D}$ and proposes a procedure for obtaining extreme points of $\mathcal{D}$ through the solution of an SDP problem. The corresponding developments for regions of guaranteed cost $\mathcal{D}^{\bar{\gamma}}$ are derived in Section IV. The numerical example is discussed in Section V. Finally, concluding remarks are presented in Section VI.

## II. Robust model predictive control employing linear matrix inequalities

The RMPC approach under consideration is concerned with uncertain state-space models of the form:

$$x(k+1) = A(k)x(k) + B(k)u(k),\ [A(k),\, B(k)] \in \Omega \quad (1)$$

where $x(k) \in \mathbb{R}^{n_x}$, $u(k) \in \mathbb{R}^{n_u}$ are the state and input variables, respectively, and $\Omega$ is an uncertainty polytope with known vertices $A_i \in \mathbb{R}^{n_x \times n_x}$, $B_i \in \mathbb{R}^{n_x \times n_u}$, $i = 1, 2, \ldots, L$. It is assumed that component-wise amplitude constraints are to be imposed on the inputs $u(k)$, as well as on $n_y$ output variables defined as $y_l(k) = C_l x(k)$ $(l = 1, 2, \ldots, n_y)$, where $C_l \in \mathbb{R}^{1 \times n}$ are known matrices.

Let $J_\infty(k)$ denote the following infinite-horizon cost function:

$$J_\infty(k) = \sum_{j=0}^{\infty} \left[ ||x(k+j|k)||_S^2 + ||u(k+j|k)||_R^2 \right] \quad (2)$$

where $S \in \mathbb{R}^{n_x \times n_x}$ and $R \in \mathbb{R}^{n_u \times n_u}$ are positive-definite weight matrices and $(\bullet|k)$ denotes a predicted value, which is computed on the basis of the information available at time $k$. It is assumed that the system state is directly measured, so that $x(k|k) = x(k)$.

The optimization problem to be solved at time $k$ can be formulated as

$$\min_{u(k+j|k),\ i\geq 0} \quad \max_{[A(k),\, B(k)]\in\Omega} J_\infty(k) \quad (3)$$

subject to

$$|u_r(k+j|k)| \leq u_{r,max},\ r = 1, 2, \ldots, n_u,\ j \geq 0 \quad (4)$$

$$|y_l(k+j|k)| \leq y_{l,max},\ l = 1, 2, \ldots, n_y,\ j \geq 1 \quad (5)$$

where $u_{r,max}$, $y_{l,max}$ denote the bounds on the magnitude of the $r$th input and $l$th output variables, respectively.

As demonstrated in [1], an upper bound $\gamma$ on the cost $J_\infty(k)$ is minimized by solving the following semidefinite programming (SDP) problem:

$$\min_{\gamma, Q>0, Y, X, Z} \gamma \quad (6)$$

subject to[1]

$$\begin{bmatrix} Q & x(k) \\ * & 1 \end{bmatrix} \geq 0 \quad (7)$$

$$\begin{bmatrix} Q & 0 & 0 & A_iQ + B_iY \\ * & \gamma I & 0 & S^{1/2}Q \\ * & * & \gamma I & R^{1/2}Y \\ * & * & * & Q \end{bmatrix} \geq 0,\ i = 1, 2, \ldots, L \quad (8)$$

$$\begin{bmatrix} X & Y \\ * & Q \end{bmatrix} \geq 0 \quad (9)$$

$$X_{rr} \leq u_{r,max}^2,\ r = 1, 2, \ldots, n_u \quad (10)$$

$$\begin{bmatrix} Z & C_l(A_iQ + B_iY) \\ * & Q \end{bmatrix} \geq 0, \quad \begin{array}{l} l = 1, 2, \ldots, n_y, \\ i = 1, 2, \ldots, L \end{array} \quad (11)$$

$$Z_{ll} \leq y_{l,max}^2,\ l = 1, 2, \ldots, n_y, \quad i = 1, 2, \ldots, L \quad (12)$$

and then using a state feedback control law $u(k+j|k) = Fx(k+j|k)$ over the prediction horizon, with $F = YQ^{-1}$. It is worth noting that the solution of this optimization problem depends on the present state $x(k)$, which appears in the first LMI (7). Therefore, in what follows the SDP given by (6) - (12) will be termed $\mathbb{P}(x(k))$.

By applying the control law in a receding horizon manner, i.e. by solving $\mathbb{P}(x(k))$ in order to obtain a new gain matrix $F$ at each sampling time $k$, the closed-loop system can be shown to be robustly asymptotically stable, provided that $\mathbb{P}(x(k))$ is feasible at the initial time $k = 0$ [1]. Henceforth, with a slight abuse of language, an initial condition $x(0) = \xi \in \mathbb{R}^{n_x}$ will be termed "feasible" if the optimization problem $\mathbb{P}(\xi)$ is feasible, i.e. if there exists a feasible solution $(\gamma, Q > 0, Y, X, Z)$ to the system of LMIs (7) - (12) with $x(k)$ replaced with $\xi$.

## III. Domain of attraction

The RMPC controller described in the previous section is a regulator that steers the system state $x(k)$ to the origin, starting from a given initial condition $x(0)$. Asymptotic stability and constraint satisfaction are guaranteed, provided that the optimization problem is feasible at the initial time $k = 0$ [1]. Therefore, the largest domain of attraction $\mathcal{D}$ of the origin for the closed-loop system can be defined as the set of all feasible initial conditions $x(0) \in \mathbb{R}^{n_x}$. Henceforth, the term "largest"

[1] Symbol $*$ is used to represent the elements below the main diagonal of a symmetric matrix.

will be omitted for brevity. In what follows, some properties of $\mathcal{D}$ will be established.

**Proposition 1** (Symmetry of $\mathcal{D}$)**.** The domain of attraction $\mathcal{D}$ is symmetric about the origin, i.e. if $\xi \in \mathcal{D}$, then $-\xi \in \mathcal{D}$.

*Proof:* Initially, it should be noted that $x(k)$ only appears in the first LMI (7) in the definition of $\mathbb{P}(x(k))$. By using the Schur complement [8], [2], the LMI (7) with $Q > 0$ is seen to be equivalent to $1 - x^T(k)Q^{-1}x(k) \geq 0$. If this inequality is satisfied with $x(k) = \xi$, it is also satisfied with $x(k) = -\xi$. Now, assume that $\xi$ is an element of $\mathcal{D}$. By definition, there exists a feasible solution $(\gamma_\xi, Q_\xi, Y_\xi, X_\xi, Z_\xi)$ to $\mathbb{P}(\xi)$. It can then be seen that $(\gamma_\xi, Q_\xi, Y_\xi, X_\xi, Z_\xi)$ is also a feasible solution to $\mathbb{P}(-\xi)$, which shows that $-\xi$ is an element of $\mathcal{D}$. ■

**Proposition 2** (Convexity of $\mathcal{D}$)**.** The domain of attraction $\mathcal{D}$ is a convex set, i.e. if $\xi_1$, $\xi_2 \in \mathcal{D}$, then $\lambda\xi_1 + (1-\lambda)\xi_2 \in \mathcal{D}$ for any $\lambda \in [0, 1]$.

*Proof:* Let $\xi_1$, $\xi_2$ be two elements of $\mathcal{D}$. Then, by definition, there exist feasible solutions $(\gamma_1, Q_1 > 0, Y_1, X_1, Z_1)$ and $(\gamma_2, Q_2 > 0, Y_2, X_2, Z_2)$ to the system of LMIs (7) - (12) with $x(k)$ replaced with $\xi_1$ and $\xi_2$, respectively. Now, let $\xi_3 = \lambda\xi_1 + (1-\lambda)\xi_2$ and $(\gamma_3, Q_3, Y_3, X_3, Z_3) = \lambda(\gamma_1, Q_1, Y_1, X_1, Z_1) + (1-\lambda)(\gamma_2, Q_2, Y_2, X_2, Z_2)$, with $\lambda \in [0, 1]$. It follows that $Q_3 = \lambda Q_1 + (1-\lambda)Q_2 > 0$. Moreover:

$$\begin{bmatrix} Q_3 & \xi_3 \\ * & 1 \end{bmatrix} = \begin{bmatrix} \lambda Q_1 + (1-\lambda)Q_2 & \lambda\xi_1 + (1-\lambda)\xi_2 \\ * & 1 \end{bmatrix} = \lambda \underbrace{\begin{bmatrix} Q_1 & \xi_1 \\ * & 1 \end{bmatrix}}_{\geq 0} + (1-\lambda) \underbrace{\begin{bmatrix} Q_2 & \xi_2 \\ * & 1 \end{bmatrix}}_{\geq 0} \geq 0 \qquad (13)$$

$$\begin{bmatrix} Q_3 & 0 & 0 & A_iQ_3 + B_iY_3 \\ * & \gamma I & 0 & S^{1/2}Q_3 \\ * & * & \gamma I & R^{1/2}Y_3 \\ * & * & * & Q_3 \end{bmatrix} = \begin{bmatrix} \lambda Q_1 + (1-\lambda)Q_2 & 0 & 0 & A_i[\lambda Q_1 + (1-\lambda)Q_2] + B_i[\lambda Y_1 + (1-\lambda)Y_2] \\ * & \gamma I & 0 & S^{1/2}[\lambda Q_1 + (1-\lambda)Q_2] \\ * & * & \gamma I & R^{1/2}[\lambda Y_1 + (1-\lambda)Y_2] \\ * & * & * & \lambda Q_1 + (1-\lambda)Q_2 \end{bmatrix}$$

$$= \lambda \underbrace{\begin{bmatrix} Q_1 & 0 & 0 & A_iQ_1 + B_iY_1 \\ * & \gamma I & 0 & S^{1/2}Q_1 \\ * & * & \gamma I & R^{1/2}Y_1 \\ * & * & * & Q_1 \end{bmatrix}}_{\geq 0} + (1-\lambda) \underbrace{\begin{bmatrix} Q_2 & 0 & 0 & A_iQ_2 + B_iY_2 \\ * & \gamma I & 0 & S^{1/2}Q_2 \\ * & * & \gamma I & R^{1/2}Y_2 \\ * & * & * & Q_2 \end{bmatrix}}_{\geq 0} \geq 0,$$

$$i = 1, 2, \ldots, L \qquad (14)$$

$$\begin{bmatrix} X_3 & Y_3 \\ * & Q_3 \end{bmatrix} = \begin{bmatrix} \lambda X_1 + (1-\lambda)X_2 & \lambda Y_1 + (1-\lambda)Y_2 \\ * & \lambda Q_1 + (1-\lambda)Q_2 \end{bmatrix} = \lambda \underbrace{\begin{bmatrix} X_1 & Y_1 \\ * & Q_1 \end{bmatrix}}_{\geq 0} + (1-\lambda) \underbrace{\begin{bmatrix} X_1 & Y_1 \\ * & Q_1 \end{bmatrix}}_{\geq 0} \geq 0 \qquad (15)$$

$$X_{3,rr} = \lambda \underbrace{X_{1,rr}}_{\leq u^2_{r,max}} + (1-\lambda) \underbrace{X_{2,rr}}_{\leq u^2_{r,max}} \leq u^2_{r,max}, \quad r = 1, 2, \ldots, n_u \qquad (16)$$

$$\begin{bmatrix} Z_3 & C_l(A_iQ_3 + B_iY_3) \\ * & Q_3 \end{bmatrix} = \lambda \underbrace{\begin{bmatrix} Z_1 & C_l(A_iQ_1 + B_iY_1) \\ * & Q_1 \end{bmatrix}}_{\geq 0} + (1-\lambda) \underbrace{\begin{bmatrix} Z_2 & C_l(A_iQ_2 + B_iY_2) \\ * & Q_2 \end{bmatrix}}_{\geq 0} \geq 0 \qquad (17)$$

$$Z_{3,ll} = \lambda \underbrace{Z_{1,ll}}_{\leq y^2_{l,max}} + (1-\lambda) \underbrace{Z_{2,ll}}_{\leq y^2_{l,max}} \leq y^2_{l,max}, \quad l = 1, 2, \ldots, n_y, \quad i = 1, 2, \ldots, L \qquad (18)$$

Therefore, $(\gamma_3, Q_3 > 0, Y_3, X_3, Z_3)$ is a feasible solution to the system of LMIs (7) - (12) with $x(k)$ replaced with $\xi_3$, which shows that $\xi_3 \in \mathcal{D}$. ■

Given the properties of convexity and symmetry about the origin, extreme points of $\mathcal{D}$ can be obtained by solving an SDP problem of the form

$$\min_{\beta, \gamma, Q > 0, Y, X, Z} \beta \qquad (19)$$

subject to

$$\begin{bmatrix} Q & \beta\xi \\ * & 1 \end{bmatrix} \geq 0 \qquad (20)$$

and the remaining LMIs (8) – (12) of the original RMPC optimization problem. In (20), $\xi \in \mathbb{R}^{n_x}$ is a constant vector that defines the direction along which the extreme point is to be found. The extreme point will be given by $\beta^*\xi$, where $\beta^*$ is the minimal value of $\beta$ resulting from the optimization process, provided that $\mathcal{D}$ is bounded along the direction of $\xi$. It is worth noting that $-\beta^*\xi$ will also be an extreme point, due to the symmetry property. Fig. 1a illustrates the process of obtaining an extreme point of $\mathcal{D}$ in a two-dimensional case ($n_x = 2$).

By solving this SDP problem with different $\xi$ vectors, a number of extreme points of $\mathcal{D}$ can be obtained. An inner approximation of $\mathcal{D}$ can then be generated as the convex hull of those points, as illustrated in Fig. 1b.

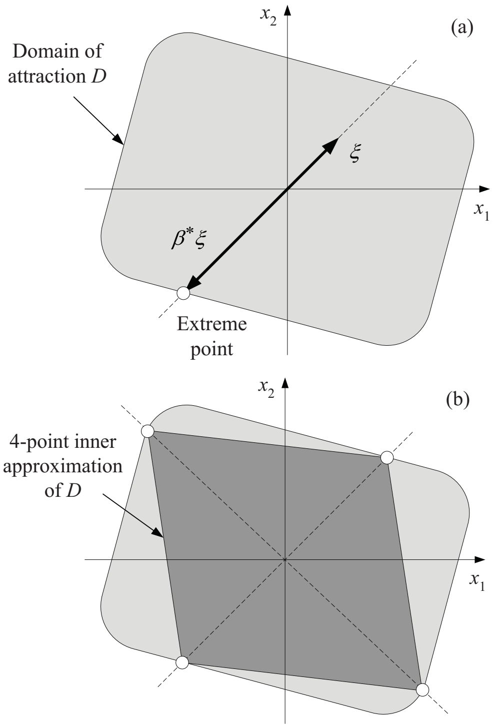

Fig. 1. (a) Determination of an extreme point of $\mathcal{D}$ through the minimization of $\beta$. (b) Inner approximation of $\mathcal{D}$ obtained as the convex hull of four extreme points.

## IV. Regions of Guaranteed Cost

The domain of attraction $\mathcal{D}$ involves only the feasibility of the RMPC optimization problem (6) – (12), regardless of the achievable value for the cost function $\gamma$. By including a constraint on $\gamma$, it is possible to characterize a region of initial conditions for which the cost is guaranteed to be smaller than a certain bound, as defined below.

**Definition 1** (Region of guaranteed cost)**.** Given a value of $\bar{\gamma} > 0$, the region $\mathcal{D}^{\bar{\gamma}}$ is defined as the set of initial conditions $x(0) \in \mathcal{D}$ for which the optimal solution $\gamma^*$ obtained by solving $\mathbb{P}(x(0))$ is smaller or equal to $\bar{\gamma}$.

The symmetry and convexity of $\mathcal{D}^{\bar{\gamma}}$ are established in the two propositions below.

**Proposition 3** (Symmetry of $\mathcal{D}^{\bar{\gamma}}$)**.** The region of guaranteed cost $\mathcal{D}^{\bar{\gamma}}$ is symmetric about the origin, for any given $\bar{\gamma} > 0$.

*Proof:* Symmetry can be demonstrated by applying the Schur complement to LMI (7), as in the proof of Proposition 1. ■

**Proposition 4** (Convexity of $\mathcal{D}^{\bar{\gamma}}$)**.** The region of guaranteed cost $\mathcal{D}^{\bar{\gamma}}$ is a convex set, for any given $\bar{\gamma} > 0$.

*Proof:* Let $\xi_1 \in \mathbb{R}^{n_x}$ and $\xi_2 \in \mathbb{R}^{n_x}$ be two elements of $\mathcal{D}^{\bar{\gamma}}$ for a given $\bar{\gamma} > 0$, and let $(\gamma_1^*, Q_1^*, Y_1^*, X_1^*, Z_1^*)$ and $(\gamma_2^*, Q_2^*, Y_2^*, X_2^*, Z_2^*)$ be the optimal solutions of $\mathbb{P}(\xi_1)$ and $\mathbb{P}(\xi_2)$. From the definition of $\mathcal{D}^{\bar{\gamma}}$, it follows that

$$\gamma_1^* \leq \bar{\gamma},\ \gamma_2^* \leq \bar{\gamma}. \tag{21}$$

Now, let $\xi_3 = \lambda\xi_1 + (1-\lambda)\xi_2$ and $(\gamma_3, Q_3, Y_3, X_3, Z_3) = \lambda(\gamma_1^*, Q_1^*, Y_1^*, X_1^*, Z_1^*) + (1-\lambda)(\gamma_2^*, Q_2^*, Y_2^*, X_2^*, Z_2^*)$, with $\lambda \in [0,1]$. In view of (21), one has $\gamma_3 = \lambda\gamma_1^* + (1-\lambda)\gamma_2^* \leq \bar{\gamma}$. Moreover, a demonstration similar to that of Proposition 2 can be used to prove that $(\gamma_3, Q_3, Y_3, X_3, Z_3)$ is a feasible solution to $\mathbb{P}(\xi_3)$. Finally, let $\gamma_3^*$ be the optimal value of the cost $\gamma$ for $\mathbb{P}(\xi_3)$. Given that the minimal value of the cost must be smaller or equal to the cost of any feasible solution, it follows that $\gamma_3^* \leq \gamma_3 \leq \bar{\gamma}$. Therefore, $\xi_3 \in \mathcal{D}^{\bar{\gamma}}$, which shows that $\mathcal{D}^{\bar{\gamma}}$ is a convex set. ■

Extreme points of $\mathcal{D}^{\bar{\gamma}}$ can be obtained by solving an SDP problem of the form

$$\min_{\beta,\gamma,Q>0,Y,X,Z} \beta \tag{22}$$

subject to

$$\gamma \leq \bar{\gamma} \tag{23}$$

$$\begin{bmatrix} Q & \beta\xi \\ * & 1 \end{bmatrix} \geq 0 \tag{24}$$

and the remaining LMIs (8) – (12) of the original RMPC optimization problem. As in the previous section, the extreme point will be given by $\beta^*\xi$, where $\xi \in \mathbb{R}^{n_x}$ is a constant vector that defines the direction along which the extreme point is to be found. An inner approximation of $\mathcal{D}^{\bar{\gamma}}$ can be generated as the convex hull of extreme points obtained with different $\xi$ vectors.

## V. Numerical example

The angular positioning system described in [1] will be adopted to illustrate the proposed method. The problem under consideration involves the control of a rotating antenna driven by an electric motor. The plant dynamics are described by the following discrete-time state equation:

$$\begin{bmatrix} x_1(k+1) \\ x_2(k+1) \end{bmatrix} = \\ \begin{bmatrix} 1.0 & 0.1 \\ 0 & 1-0.1\alpha(k) \end{bmatrix} \begin{bmatrix} x_1(k) \\ x_2(k) \end{bmatrix} + \begin{bmatrix} 0 \\ 0.0787 \end{bmatrix} u(k) \tag{25}$$

where the state variables $x_1$ and $x_2$ denote the angular position ($rad$) and velocity ($rad/s$) of the antenna, respectively, and the control variable $u$ corresponds to the input voltage ($V$) of the electric motor. The viscous friction in the moving parts of the antenna is associated to the uncertain parameter $\alpha(k)$, which is assumed to be in a given range $[\alpha_{min}, \alpha_{max}]$. Therefore, the model is of the form (1), with $A(k) \in Co\{A_1, A_2\}$ where

$$A_1 = \begin{bmatrix} 1.0 & 0.1 \\ 0 & 1-0.1\alpha_{min} \end{bmatrix},\ A_2 = \begin{bmatrix} 1.0 & 0.1 \\ 0 & 1-0.1\alpha_{max} \end{bmatrix} \tag{26}$$

It is worth noting that the actual dependence of $\alpha(k)$ on the time $k$ does not affect the RMPC formulation, because the LMIs only involve the vertices $A_1$, $A_2$ of the uncertainty polytope. In what follows, the uncertain parameter will be denoted simply by $\alpha$ for brevity.

The cost function weights $S$ and $R$ were set to $I_{2\times 2}$ and 1, respectively. Moreover, the control variable $u$ was constrained to the range $[-2V, +2V]$, as in [1], and the position $x_1$ was constrained to the range $[-1rad, +1rad]$. Such a constraint can be cast into the form (5) by defining an output variable $y = Cx$, with $C = [1\ 0]$. All numerical results were obtained by using the LMI Lab package for Matlab.

### A. Results

Figure 2a presents the inner approximations of the attraction domain $\mathcal{D}$ obtained by using 4 and 16 extreme points. In this case, the bounds on the uncertain parameter $\alpha$ were set to $\alpha_{min} = 0.1$ and $\alpha_{max} = 10$. Moreover, Fig. 2a shows a grid of states that were employed to test the feasibility of the original SDP problem (6) - (12). As can be seen, all grid points inside the obtained polygons correspond to feasible initial conditions. It is worth noting that points $[-1\ 0]^T$ and $[+1\ 0]^T$, which correspond to unfeasible initial conditions, are outside the polygons, as shown in Fig. 2b. The use of 16 extreme points provides a better approximation of the attraction domain, in that the resulting polygon encompasses a larger region of feasible initial conditions, as compared to the 4-point approximation.

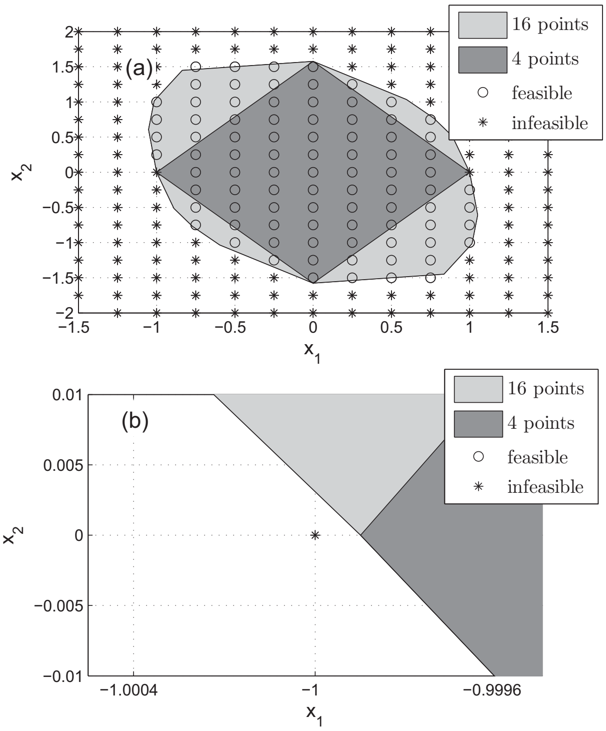

Fig. 2. (a) Inner approximations of the attraction domain $\mathcal{D}$. (b) Detail of the region around point $[-1\ 0]^T$.

From a physical point of view, unfeasibility arises if the position $x_1$ is close to the ±1 bounds and the velocity is such that the position is changing towards the bound. It is interesting to notice that part of the 16-point polygon is located outside the $[-1, +1]$ range of admissible values for $y = x_1$. This result can be explained by noting that the output constraints in (5) are only enforced after one time step ahead of the present time. Therefore, if the initial condition is such that the output $y$ can be steered to the admissible range in a single time step, the output constraint in (5) will be satisfied.

An interesting investigation that could be performed at this point concerns the relation between the domain of attraction $\mathcal{D}$ and the range of values for the uncertain model parameter $\alpha$. It is expected that $\mathcal{D}$ will be larger if the characterization of $\alpha$ is more precise, i.e., if the range of uncertainty is smaller. To investigate this issue, the proposed method was employed to obtain new extreme points of $\mathcal{D}$, with bounds on $\alpha$ set to $\alpha_{min} = 0.5$ and $\alpha_{max} = 2$. The results are presented in Fig. 3. As expected, the polygon obtained for $0.5 \leq \alpha \leq 2$ contains the polygon obtained for the wider range $0.1 \leq \alpha \leq 10$.

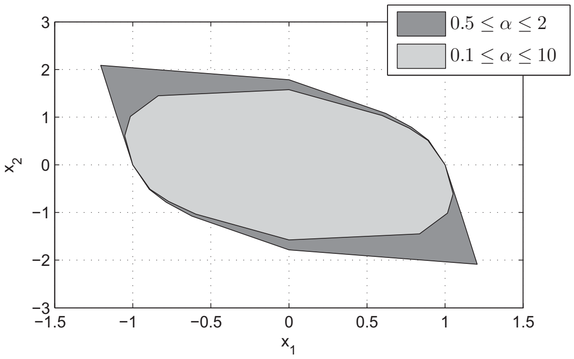

Fig. 3. Inner approximations of the attraction domain $\mathcal{D}$ for two different uncertainty ranges.

Figure 4 presents the inner approximations of the region of guaranteed cost $\mathcal{D}^{\bar{\gamma}}$ obtained by using 4 and 16 extreme points with $\bar{\gamma} = 100$. In this case, the bounds on the uncertain parameter $\alpha$ were again set to $\alpha_{min} = 0.1$ and $\alpha_{max} = 10$. The grid of states shown in this figure was employed to solve the SDP problem (6) - (12) in order to obtain the minimal value of $\gamma$, which is denoted by $\gamma^*$. As expected, all grid points inside the obtained polygons correspond to initial conditions for which $\gamma^* \leq \bar{\gamma} = 100$. As in Fig. 2a, the use of 16 extreme points provides a better approximation of the region under consideration.

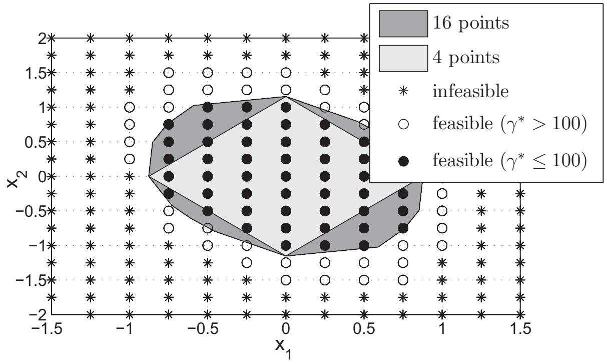

Fig. 4. Inner approximations of the region of guaranteed cost $\mathcal{D}^{\bar{\gamma}}$ for $\bar{\gamma} = 100$.

Figure 5 shows the 16-point polygons obtained for different values of $\bar{\gamma}$. As can be seen from these inner approximations, the region of guaranteed cost $\mathcal{D}^{\bar{\gamma}}$ tends to increase with $\bar{\gamma}$. It can also be seen that, as $\bar{\gamma}$ is increased, $\mathcal{D}^{\bar{\gamma}}$ converges to the domain of attraction $\mathcal{D}$. Indeed, if $\bar{\gamma}$ is made arbitrarily large, the SDP problem becomes equivalent to that involved in the determination of extreme points for $\mathcal{D}$ (i.e. without the $\gamma$ constraint in (23)).

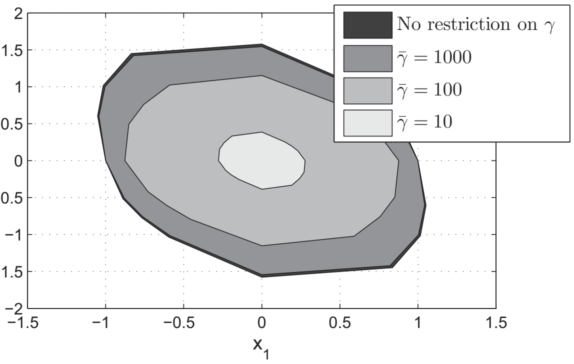

Fig. 5. Inner approximations of the region of guaranteed cost $\mathcal{D}^{\bar{\gamma}}$ for different values of $\bar{\gamma}$. The region obtained with no restriction on $\gamma$ is an inner approximation of $\mathcal{D}$.

Finally, Fig. 6 presents the 16-point polygonal approximations to the region $\mathcal{D}^{\bar{\gamma}}$ for $\bar{\gamma} = 100$ and two different ranges for the uncertain parameter $\alpha$, namely $0.1 \leq \alpha \leq 10$ and $0.5 \leq \alpha \leq 2$. As in the case of the attraction domain, the region of guaranteed cost increases as the uncertainty range is reduced.

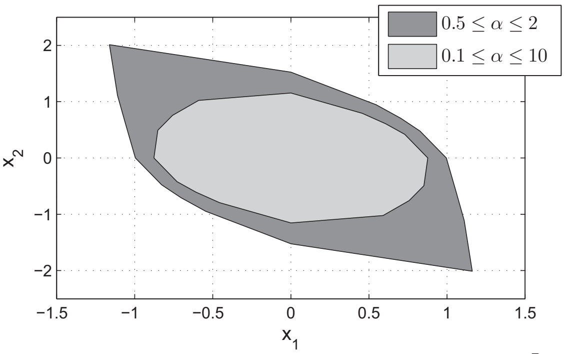

Fig. 6. Inner approximations of the region of guaranteed cost $\mathcal{D}^{\bar{\gamma}}$ for $\bar{\gamma} = 100$ and two different uncertainty ranges.

## VI. Concluding Remarks

This paper demonstrated some properties of the domain of attraction $\mathcal{D}$ and regions of guaranteed cost $\mathcal{D}^{\bar{\gamma}}$ for the LMI-based RMPC formulation originally proposed in [1]. More specifically, $\mathcal{D}$ and $\mathcal{D}^{\bar{\gamma}}$ were shown to be convex and symmetric about the origin, which allowed the determination of extreme points through the solution of modified versions of the original SDP problem involved in the RMPC formulation. Inner approximations of these sets could then be generated as the convex hull of the extreme points. In the numerical example presented for illustration, such approximations were found to be in agreement with the feasibility and cost results obtained in a pointwise manner for a grid of initial conditions.

Future investigations could be concerned with the extension of the present work to other LMI-based RMPC formulations with less conservatism, such as those proposed in [17], [18], [19], [20]. It is expected that a reduction in conservatism should lead to an enlargement in the domain of attraction, as well as the regions of guaranteed cost, which would be an additional advantage of those formulations with respect to [1].

*Abstract*—**Polarization-induced Phase distortion happens in the distributed dual Mach-Zehnder fiber interferometric sensing system, which results in big locating errors. Based on the investigation in the cause, we propose and demonstrate a scheme using automatic polarization controller together with simulated annealing as control algorithm to obtain high positioning accuracy in the system. Through laboratory experiments, the key parameters of the algorithm are analyzed and the optimal settings of them are fixed. Field trial results show that this method can make a fast search for the optimal state of polarization and maintain the strong signal correlation for a long time.**

***Keywords-Distributed sensor, polarization control, Mach-Zehnder fiber interferometer, polarization, simulated annealing***

## I. INTRODUCTION

With the exploitation of oil and gas resources as well as the surge in energy demand, the total pipeline mileage is growing constantly, and pipeline safety has become an important research topic. Our group has developed the distributed oil and gas pipeline leak detection and pre-warning system based on dual Mach-Zehnder Optical Fiber Interferometer for detecting and locating intrusions which may threaten pipeline safety[1]. Positioning the illegal invasion, as a key technology in the system, uses cross-correlation function to estimate time delay which requires strong correlation between signals. However, due to the phenomenon of polarization-induced fading which can cause phase distortion, correlation bewteen detection singals often degenerates and big locating errors then arise in pratical applications[2].

To solve the problem, passive phase demodulation method was studied in previous papers, in which the vibration phase signal are demodulated from every two original signals and thus avoid the negative effect of polarization-induced phase shift.[3] However, as this method costs much time in signal processing, it's hardly suitable in practical applications which demand good real-time performance. In this paper we propose and demonstrate a new method based on polarization control to eliminate phase distortion and furthermore to increase positioning accuracy of the system.

The existing polarization control algorithms mainly aim to eliminate the polarization mode dispersion(PMD) in the optical fiber and polarization dependent modulation(PDM) in the electrooptical modulator(EOM)[4],[5]. These feedback control algorithms are based on the peak value search of light intensity and can get control effect instantly with the output of control words. In the dual Mach-Zehnder interferometric system, however, the polarization control objective is the correlation between two detection signals which is not directly related to the light intensity. Therefore, the above mentioned algorithms can not apply to the pipeline security monitoring system. In this paper, the simulated annealing(SA) based on the correlation coefficient between two detection signals is employed as the polarization control algorithm to search for the input polarization operating point which results in little degeneration of detection signals' correlation. Field experiments show that the algorithm can rapidly find the operating point and continuously stabilize the correlation between the system detection signals.

## II. RESEARCH ON THE CAUSE

Fig. 1 shows the equivalent optical path of the dual Mach-Zehnder fiber interferometer sensing system.

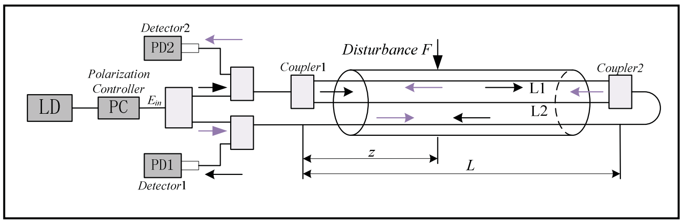

Figure 1. Conventional diagram of dual Mach-Zehnder system structure

The system input light can be represented by the Jones vector:

$$E_{in} = \begin{bmatrix} E_x \\ E_y \end{bmatrix} = E_0 \begin{bmatrix} \cos\theta\cos\varepsilon - j\sin\theta\sin\varepsilon \\ \sin\theta\cos\varepsilon + j\cos\theta\sin\varepsilon \end{bmatrix} \qquad (1)$$

Where $E_0$ denotes the lightwave amplitude, $\theta$ and $\varepsilon$ are the azimuth and ellipticity angle respectively which determine the input polarization state together.

978-1-4673-1560-9/12/$31.00 ©2012 IEEE

Assuming that the forward and backward equivalent Jones Matrices of the two sensing arms are separately $E_1$,$E_2$ and $E_1^T$ ,$E_2^T$ which are determined by polarization property of the sensing fiber, the optical signals detected by photodetectors PD1 and PD2 can be represented by:

$$\begin{cases} E_{out1}=\left(E_1+E_2\cdot e^{j\delta(t)}\right)\cdot E_{in} \\ E_{out2}=\left(E_1^T\cdot e^{j\delta(t)}+E_2^T\right)\cdot E_{in} \end{cases} \tag{2}$$

Where $\delta(t)$ is the phase retardation difference between two sensor fibers caused by disturbance. The light intensity signals $I_1(t)$、$I_2(t)$ can be represented by:

$$\begin{cases} I_1(t)=\left|E_{out1x}\right|^2+\left|E_{out1y}\right|^2=I_0\cos\left[\delta(t)+f_1\left(\theta,\varepsilon,\alpha\right)\right] \\ I_2(t)=\left|E_{out2x}\right|^2+\left|E_{out2y}\right|^2=I_0\cos\left[\delta(t)+f_2\left(\theta,\varepsilon,\beta\right)\right] \end{cases} \tag{3}$$

Where $I_0$ is the light intensity of light source, $\alpha$ and $\beta$ are the polarization induced phase shift caused by fiber birefringence respectively in forward and backward fiber path.

Taking the length of time $t$ of the detected signals, the correlation coefficient between two channel signals is calculated by the following formula:

$$\rho_{xy}=\frac{\int_0^t I_1(t)I_2(t)dt}{\left[\int_0^t I_1^2(t)dt\int_0^t I_2^2(t)dt\right]^{\frac{1}{2}}}=\frac{\int_0^t \cos^2\left(\delta(t)+f_1\left(\theta,\varepsilon,\alpha\right)\right)\cdot\cos^2\left(\delta(t)+f_2\left(\theta,\varepsilon,\beta\right)\right)dt}{\left[\int_0^t \cos^2\left(\delta(t)+f_1\left(\theta,\varepsilon,\alpha\right)\right)dt\cdot\int_0^t \cos^2\left(\delta(t)+f_2\left(\theta,\varepsilon,\beta\right)\right)dt\right]^{\frac{1}{2}}} \tag{4}$$

The correlation coefficient $\rho_{xy}$ is mainly determined by the phases of two detected signals, so it's feasible to alter the correlation between signals through changing the additional phase differences $f_1(\theta,\varepsilon,\alpha)$ and $f_2(\theta,\varepsilon,\beta)$. Since the additional phase difference are determined together by the input polarization state, the polarization property of fiber and the system laying environment in which the latter two are difficult to adjust artificially, it can only be changed by altering the input polarization state.

Fig. 2 shows the various interference light intensity in different input light polarization state which are respectively linearly polarized($\theta$=0.25π, $\varepsilon$=0), elliptically polarized($\theta$=0.25π, $\varepsilon$=0.25π), and circularly polarized($\theta$=0.25π, $\varepsilon$=0.125π) and $\delta(t)$ is assumed changing from -2π to 2π. From Fig 2, we can confirm that not only the amplitude but also the phase of the signal varies in different input polarization states. It's conceivable that there must be one input polarization state or several of them which can decrease the additional phase difference to an acceptable range. Therefore, it's feasible to improve the correlation between the detection signals by controlling the polarization state of input light and searching for the specific one as mentioned above.

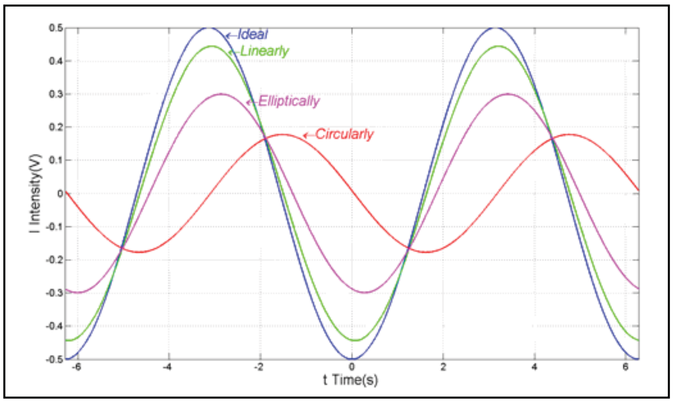

Figure 2. The interference light intensities in different input polarization states

## III. ALGORITHM CLARIFICATION

### *A. Algorithm Principle*

Setting correlation coefficient $\rho_{xy}$ as the objective function, the polarization control model can be represented by:

$$\max(\rho_{xy})=f(X) \qquad X\in\Theta \tag{5}$$

Where $X$ denotes a combination of the polarization controller's retardation $x_i$(i=1,2,3,4). It's an optimization problem which requires global search capability of the control algorithm. simulated annealing[6]-[8] can probabilistically jump out of local optimum and achieve global optimum according to Metropolis criterion and thus is applied as the feedback control algorithm. The initial solution $X_i$ is randomly generated whose objective function value is $f(X_i)$ and the new solution $X_j$ is generated by state generator function whose objective function value is $f(X_j)$. The probability of accepting the new solution $p_r$ is determined by the Metropolis criterion[7]:

$$p_r\left(X_i\Rightarrow X_j\right)=\begin{cases}1 & f\left(X_j\right)\le f\left(X_i\right) \\ \exp\left(-\dfrac{f\left(X_j\right)-f\left(X_i\right)}{T_k}\right) & f\left(X_j\right)>f\left(X_i\right)\end{cases} \tag{6}$$

Where $T_k$ is the current temperature state. Comparing $p_r$ with a random number which ranges between 0 and 1, if $p_r$ is larger, the new solution $X_j$ is accepted, otherwise $X_i$ is retained. After specified rounds of solution changing, local optimum polarization state under current temperature state can be found. Then $T$ value is gradually reduced according to the temperature update function and local optimum solution under every temperature state can be derived. When $T$ value is close to zero, calculation stops and current optimum solution is global optimum solution. The temperature update function is defined as:

$$T_{k+1}=p\cdot T_k \tag{7}$$

Where the temperature update coefficient $p$ has a range of 0-0.95[8].

Since the phase retardation caused by polarization controller in practice has a range of 0-5π which means the solution space is bounded. We define the state generator function as follows:

$$X_{i+1} = \begin{cases} X_i - f(X_i)\cdot s & X_i \geq 5\pi \\ X_i + f(X_i)\cdot c\cdot s & 0 < X_i < 5\pi \\ X_i + f(X_i)\cdot s & X_i \leq 0 \end{cases} \tag{8}$$

Where *s* is searching step size, *c* is plus or minus one randomly.

### *B. Setting of Key Parameters*

Simulated annealing algorithm performance does not rely on the value of initial solution but can be affected by settings of key parameters such as the initial temperature $T_0$, the search step size *s* in the state generator function and the temperature update coefficient *p*.

In order to obtain the optimum setting of key parameters so as to ensure the global search capability of the control algorithm, experiments have been carried out to test the optimization in different parameter settings.

Fig. 1 shows the installation position of the polarization controller which can control both the forward and backward optical path and avoid changing the system structure as well. The model of the polarization controller applied is polaRITE Ⅲ from General Photonics.

#### *1) The choice of the initial temperature*

In simulated annealing algorithm, higher initial temperature $T_0$ will enhance the probability of obtaining high quality solution but increase the number of outer loop at the same time. With comprehensive consideration of both quality and efficiency of optimization, the range of $T_0$ is set less than one.

Fig. 3 shows the different search areas in Poincare Sphere with different initial temperature settings in stimulated annealing algorithm. When $T_0$ is small, the algorithm can only search part of the region in Poincare Sphere with a large blind area. According to the experiment results, the initial temperature is set as 1.

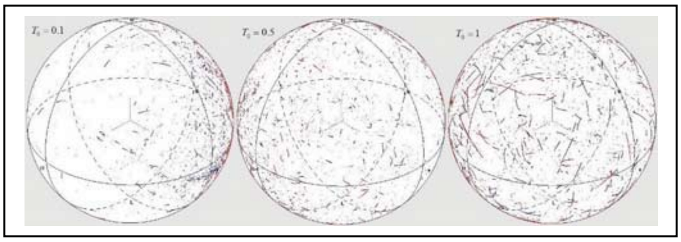

Figure 3. Initial temperature effect on search area, $T_0$=0.1,0.5,1.

#### *2) The choice of temperature update coefficient*

Simulated annealing is a process of temperature slowly decreasing in which higher value of temperature update coefficient *p* will bring about a larger searching area but lower convergence rate .

Fig. 4 shows the different search areas in Poincare Sphere with different settings of *p* in stimulated annealing process. Since they do not have much difference as Fig. 4 shows, taking into account that the higher value of *p* will slow down the convergence speed and then degrade the real-time performance of the system, the temperature update coefficient is set as 0.5.

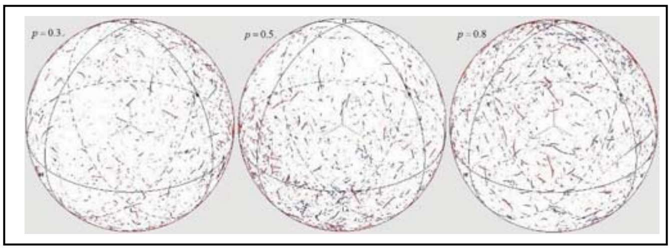

Figure 4. Temperature update coefficient effect on search area, *p*=0.3,0.5,0.8.

#### *3) The choice of search step size*

State generator function determines whether the system can search for the optimal value in the whole solution space. Large step size brings about big change of the solution which may deviate from the solution space, while small one brings about little change of the solution which can hardly jump out of local optimum to achieve global optimum.

Fig. 5 shows the effects of different settings of search step size. When *s* increases to 1.10 can it jump out of local optimum and search the whole Poincare Sphere. Therefore, *s* is set as 1.10.

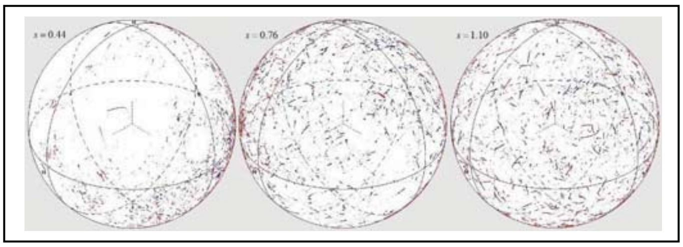

Figure 5. Search step size effect on search area, *s* =0.44,0.76,1.10.

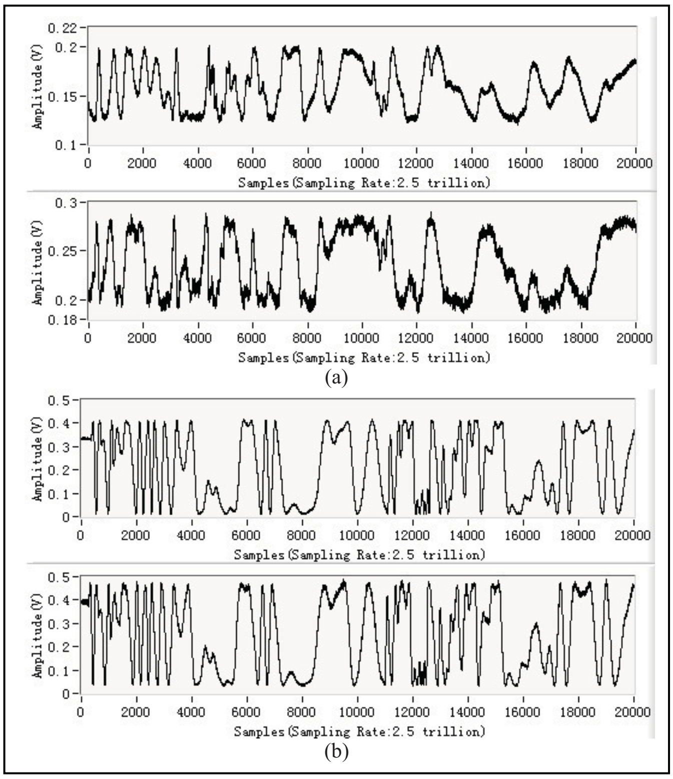
## IV. FIELD EXPERIMENT VERIFICATION

The approach is applied in the oil pipeline safety monitoring and pre-warning system which covers a monitoring distance of 43km.

Fig. 6 shows the contrast between the original detection signal waveforms with and without employment of the polarization control method. When the approach is not applied, the signals in Fig. 4(a) has a calculated correlation coefficient $\rho_{xy}$ =0.28, with employment of the polarization control approach, the correlation coefficient is 0.95 as shown in Fig. 4(b).

Fig. 7 shows the correlation coefficient between detection signals within 24 hours recorded every second after using the polarization control method. which verifies the stability of the approach.



(a)

(b)

Figure 6. Origianl detection signal waveforms. (a)Polarization control is not applied. (b)Polarization control is applied.

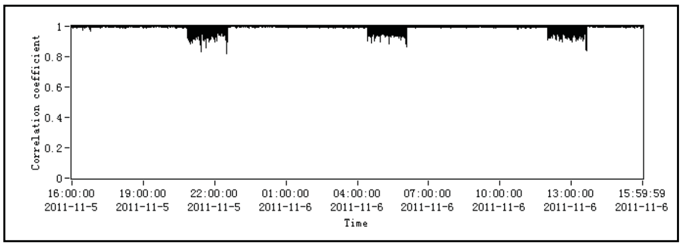


Figure 7. Correlation coefficient within twenty-four hours under polarization control.

## V. CONCLUSION

Based on the investigation in the cause of positioning errors, we present a new approach to solve the degeneracy problem of detection signals' correlation in the distributed dual Mach-Zehnder fiber interferometric sensing system using automatic polarization controller together with simulated annealing as control algorithm. Using correlation coefficient between two detection signals as the feedback quantity, this method can control the input polarization state in real-time and find the operating point rapidly when the correlation between signals degenerates. Through laboratory experiments, the key parameters of the algorithm are analyzed and the optimal settings of them are fixed. Field trial shows significant improvement and stability of the correlation between detection signals after employing the approach.

*Abstract*—**The Rigid Internal Fixation is one of the commonly used methods to reconstruct the mandible in bone repair surgery. This research proposed a complete flow of the designing and Finite Element Analysis (FEA).The customized titanium plate and screws model were imported in Mimics, then fitted and simulated with the shape of mandible 3D model. The simulation model would be imported into Magic's and the screw holes were located and punched. In order to ensure the validity of model for surgical guidance, the FEA was employed by FEA software Abaqus in this study. Different angles were selected and different loads were loaded. Comparing with the nomal mandible mechanical data, the von mises stress and deformation which was from the reconstruction of mandible were in the regular range and the RP model which would be used in the medical guidence was manufactured according to the 3D model. The research for this processing has important guide significance and good business prospects.**

***Keywords-customized ti-plate, fixation and simulation, FEA in Abaqus, model buliding***

## I. INTRODUCTION

The reconstruction of mandible is a great challenge in oral and maxillofacial surgery. The loss of mandibular bone leads to severe deformation and dysfunctions such as swallowing, chewing and speaking. Usually bone defects in mandible region are caused by tumors and bone infections [1]. The traditional reconstruction plates are difficult to form into the mandible anatomical shape. Plate failures always occur at the plate bending area and usually lead to unsatisfactory functional results to patients. Because of the complexity of human anatomy and individual difference in general, the construction of true anatomical model based on the individual patient has great significance. Combining with image processing and visualization techniques, the customized model as well as the finite element biomechanical simulation model has possibility to be established by medical images which have no trauma. The customized biomechanical modeling based on CT images provides accurate and simple way to establish the finite element model of organisms which try its best to be faithful to the customized anatomy structure and simulate the biomechanical behavior of living tissue with high precision.

In this study, the mandible reconstruction was conducted by using the segmental fibulas, which were similar to the defect of mandible in morphology and fixed by titanium plate and screws. This method involves Rigid Internal Fixation (RIF), which takes bony cortex of lateral law as basis of fixation. Michelet et al. (1973) proposed the notion of simple cortex of bone osteosynthesis. RIF achieves rigid fixing in 3D and has the advantages of fast healing, no external callus and direct cicatrization.

In order to fix the reconstruction mandible with the fibular, a customized titanium plate will be designed. The reconstructive mandible FE model will be established and prepare to be analysed in Abaqus. After the mandible reconstructed, the mandible model will be disposed by a Finite Element Analysis. Comparing with the normal mandible mechanical data, if the FEA data is regular, the RP model will be manufactured according to the 3D model. The whole process is represented by the Fig.1.

As in engineering, the initial work with FEA in medicine was the analysis of the macroscopic solid structures [2].The FEA was also used some years ago to predict dental implant loading [3], [4] and for micro structural analysis [5].

## II. METHODS

### A. Mandible Fixation and Simulation.

The reconstructive mandible 3D virtual model was established from the patient's CT data in Mimics [6].According to the mandible shape, the customized titanium plate was modeling in Pro/E condition. The titanium screw model also was built and assembled with the titanium plate. In order to accurately conduct FEA, the thread should be omitted to prevent irregular triangles and other errors appearing. It was the titanium screw model in Fig.2 and the assembly of titanium plate and titanium screws was in Fig.3.

The assembled titanium plate and titanium screws were imported Mimics with STL format, then fitted and simulated with the shape of mandible 3D model as shown in Fig. 4.

After the simulation, the 3D model would be input Magics software (Materialise, Inc., Leuven, Belgium). Depending on the location of titanium screws, the screw holes would be located and punched as shown in Fig. 5 and Fig.6. In Magics, the STL file was edited and simplified so that it was only one shell and contained a regular and reduced number of triangles.

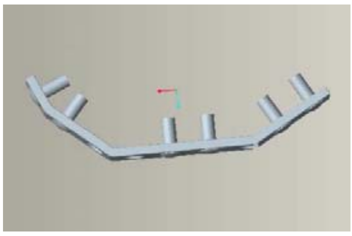

Figure 3. Assembly of titanium plate and titanium screws

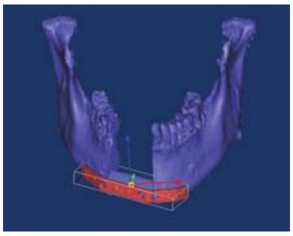

Figure 4. Fitting of titanium and mandible 3D model

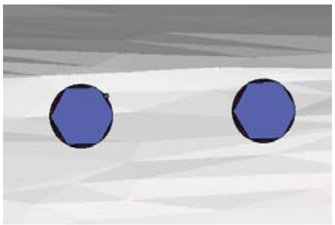

Figure 5. Screw holes

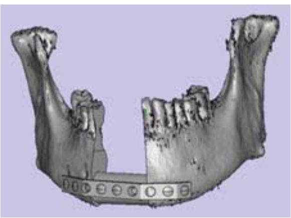

Figure 6. Reconstructive mandible and titanium plate

This research has its advantage of mandible fixation and simulation. The screw holes were punched firstly in traditional CAD model, then the titanium screws were located depending on the screw holes. In this research, the mandible shape was irregular and the titanium plate and titanium screws were modeling in Pro/E condition. If one screw hole was located and punched at first, the location of the next screw hole must be wrong because the titanium plate is limited. Contrary to the traditional way, the assembly of titanium plate and titanium screws was located at first, then the screw holes would be fixed and punched depending on the titanium screws. This method ensures the accuracy of screw hole’s location in this non-traditional CAD model.

### *B. FE Model Establishment*

In Magics, the repaired model was imported to the remeshing module which could divide the model into triangle meshes and finish the repair and optimization, and then the preprocessing documents of finite element method were exported. In this paper, a nonlinear finite element analysis software named Abaqus was adopted, so the exported document should be stored as .inp. Then the .inp model would be imported into Abaqus and converted from triangular meshes to tetrahedral meshes through the mesh module of Abaqus. The mesh model is shown in Fig.7. The tetrahedral meshes totally had 138866 tetrahedral elements and 30586 nodes as shown in Table I.

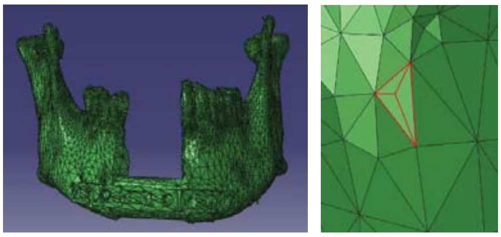

Figure. 7. Reconstruction mandible after remeshed and its grid cell

TABLE I. PARAMETER OF MANDIBLE FE MODEL

| Number of nodes | Number of elements | Element types |
|---|---|---|
| 30586 | 138866 | C3D4 |

### C. *Property*

In Abaqus, a new job in FE model would be created and exported to Mimics with .inp file. The property was given by module which the Mimics came with. The following is the formula for calculating the property parameters.

$$\begin{cases}\text{Density} = \text{-}13.4 + 1017 \times \text{Grayvalue} \\ \text{E - Modulus} = \text{-}388.8 + 5925 \times \text{Density}\end{cases} \qquad (1)$$

After the property was given completely, the model should be exported from Mimics to Abaqus with .inp file. Examining the property module, the model's color had turned light blue, which proved that the property was given successfully. The model with property is shown in Fig.8.

This is the essence: CT images of bone were calculated according to the pixel and the CT value would be obtained. The density of each part would be got from CT value and the property parameters of each skeletal part could be calculated successfully relying on the formula (1).The mandible consists of many composite biomaterials,so endowing property artificially would caused unexpected inaccuracy and errors. Comparing with the artificial way, it is a good choice to endow property with Mimics software.

### D. *Loading and Boundary Condition*

Before the FE model was done an analysis, the loading and boundary condition need to be set.

Boundary constraint is a very important issue related to the accuracy of FE model. The exactness or not of boundary constraint will directly affect the accuracy of the result. The perfect instance is that all boundary conditions are the same with actual instance, but it is almost impossible owing to the complex configuration. Therefore, the boundary conditions need to be predigested. As to the definition of mandibular boundary conditions, there was no uniform conclusion. Li ling et.al [7] achieved reasonable result with such boundary conditions: the mandibular lower edge as the underside boundary, acetabulum plane as the upside boundary and back of mandibular rise-offset as definition. This paper set the boundary conditions as shown in Fig. 9.

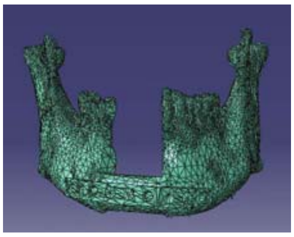

Fig.ure 8. Model with property

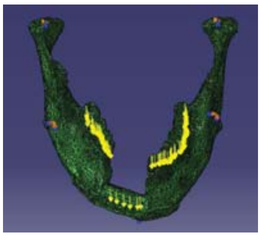

Figure 9. Loading and boundary conditions

The left tooth and the fibular surface were loaded in this analysis. The following are the boundary conditions.

$$\begin{cases}\text{acetabulum plane:} \\ ZASYMM\big(\ U1 = U2 = UR3 = 0\big) \\ \text{The reconstructive mandible middle line:} \\ XSYMM\big(\ U1 = UR2 = UR3 = 0\big) \\ \text{The mandible trailing edge:} \\ ENCASTRE\big(\ U1 = U2 = U3 = UR1 = UR2 = UR3 = 0\big)\end{cases}$$

### E. *Finite Element Analysis in Abaqus*

According to the actual mandibular occlusal force condition, the elastic mechanics theory was used to analyze the mandibular biomechanics. Spatial problem has 15 unknown numbers: six stress components $\sigma_x$ 、 $\sigma_y$ 、 $\sigma_z$ 、 $\tau_{yz} = \tau_{zy}$ 、 $\tau_{zx} = \tau_{xz}$ 、 $\tau_{xy} = \tau_{yx}$ ; six deformation components $\xi_x$ 、 $\xi_y$ 、 $\xi_z$ 、 $\gamma_{yz}$ 、 $\gamma_{zx}$ 、 $\gamma_{xy}$ ; three displacement components $u$ 、 $v$ 、 $w$ . These 15 unknown functions should meet the 15 basic equations.

The space problem of equilibrium differential equation:

$$\left.\begin{aligned}\frac{\partial\sigma_x}{\partial x} + \frac{\partial\tau_{yx}}{\partial y} + \frac{\partial\tau_{zx}}{\partial z} + f_x = 0 \\ \frac{\partial\sigma_y}{\partial y} + \frac{\partial\tau_{zy}}{\partial z} + \frac{\partial\tau_{xy}}{\partial x} + f_y = 0 \\ \frac{\partial\sigma_z}{\partial z} + \frac{\partial\tau_{xz}}{\partial x} + \frac{\partial\tau_{yz}}{\partial y} + f_z = 0\end{aligned}\right\} \qquad (2)$$

According to the elastic mechanics theory, the elastomer stress boundary condition:

$$\left.\begin{aligned}l(\sigma_x)_s + m(\tau_{yx})_s + n(\tau_{zx})_s = \overline{f_x} \\ m(\sigma_y)_s + n(\tau_{zy})_s + l(\tau_{xy})_s = \overline{f_y} \\ n(\sigma_z)_s + l(\tau_{xz})_s + m(\tau_{yz})_s = \overline{f_z}\end{aligned}\right\} \qquad (3)$$

It demonstrated the relationship between the stress components of the boundary value and the plane force components [8].

Considering the above points, the steps were set for Finite Element Analysis after importing mandibular model into Abaqus. Two steps were set separately to raise the simulation reality. In order to raise the load regularly, the first step load is set low, while the second normal. This research mainly analyzed the force of chewing, as the force of not chewing was too low to consider; thus, we adopt Static-General analysis.

Calculation formula of Von Mises ( $\sigma_e$ ) is：

$$\sigma_e=\left\{\frac{1}{2}\left[\left(\sigma_1-\sigma_2\right)^2+\left(\sigma_2-\sigma_3\right)^2+\left(\sigma_3-\sigma_1\right)^2\right]\right\}^{\frac{1}{2}} \qquad (4)$$

$\sigma_1$ 、 $\sigma_2$ 、 $\sigma_3$ is the first, second and third principal stress [8].

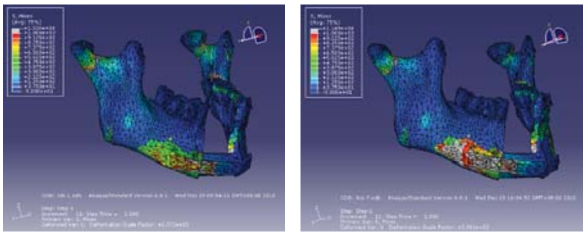
### F. *Results and Discussion*

When occluding, chewing muscles drive teeth to chew the food so as to make the mandible suffer load; and when not occluding, mandible hardly support load. Therefore, the analysis of mandibular force is mainly the force analysis of occluding. Bai shizhu, Li dichen et.al [9] applied force on the occluding plane to FEA the mandible, and got relatively accurate result.

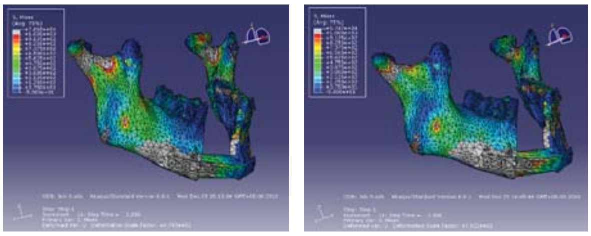
In this study, the force was applied separately in the direction of vertical, 45° with the occluding plane (teeth force range when occluding) to analyze the force. The load magnitudes are 100N and 500N.

Depending on the magnitude of the load and the analysis of different loading directions, we got reconstruction mandible stress simulation results as shown in the reconstruction of mandibular force after the simulation process. The maximum stress was at mandibular condylar neck.

According to the Von Mises stress diagram of reconstructive mandible, we can get the results
with the magnitude of load increasing, right side of the mandible and fibula junction, and the mandible condyle the stress concentration region increased. The maximum stress of the Von Mises stress diagram of reconstructive mandible increased as the load increased gradually. The Von Mises stress is shown in Fig.10.



（A）100N-0° （B）100N-45°



（C）500N-0° （D）500N-45°

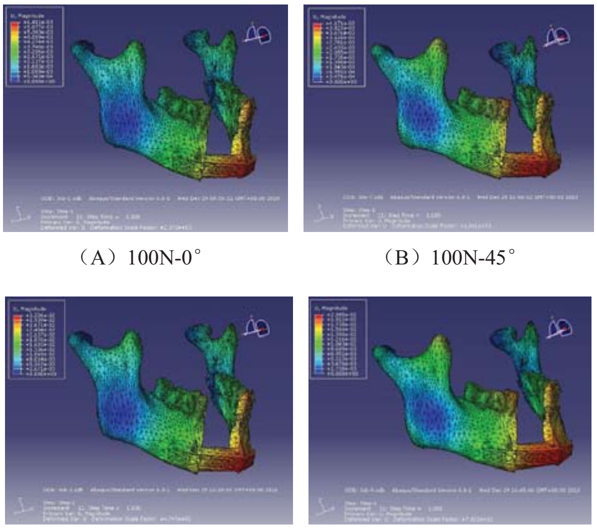
Figure 10. Result of reconstructive mandible Von Mises stress on different conditions

Reference to the classification criteria from Urken et al [10], this model belongs to B-type damage. Based on the results from Abaqus, the maximum stress of the Von Mises is shown in Table II.

TABLE II. MAXIMUM STRESS OF THE VON MISES

| Angles and loads | Maximum stress of the Von Mises (Mpa) |
|---|---|
| 100N-0° | 0.01534 |
| 500N-0° | 0.07668 |
| 100N-45° | 0.01149 |
| 500N-45° | 0.05747 |

According to the deformation results, with the magnitude of load increasing, the maximum deformation increased at the mandible midline. The mandible maximum deformation was increasing as the load was increasing gradually. The mandible deformation is shown in Fig.11.



（A）100N-0° （B）100N-45°

（C）500N-0° （D）500N-45°

Figure 11. Result of reconstructive mandible deformation on different conditions

The maximum deformation was at left side of the mandible and fibula junction and it is shown in Table III.

TABLE III. MAXIMUM DEFORMATION

| Angles and loads | Maximum deformation (mm) |
|---|---|
| 100N-0° | 0.06411 |
| 500N-0° | 0.32060 |
| 100N-45° | 0.04171 |
| 500N-45° | 0.20850 |

## III. Model building

Refer to the reference [11], the von mises stress and deformation were in the regular range and the RP model can be manufactured with 3DP rapid prototyping which is from Israel. The model with support materials is shown in Fig.12 and the model removing support materials is shown in Fig.13. The doctor could measure kinds of datum and practice operation to enhance the efficiency and success rate of surgery by 3D model which had been manufactured.

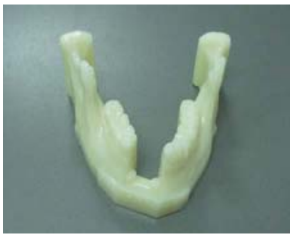


Figure 12. Model with support materials

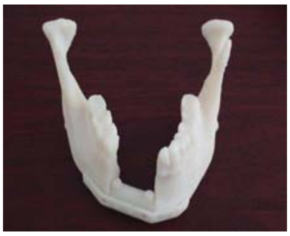

Figure 13. Model without support materials

## IV. Conclusions

Sekou Singare and Dichen Li [12] had established the mandible model successfully with CT data and curve fitting. The RP model had been manufactured at first, then the mold would be reproduced. After that, the titanium implant had been casted and implanted into the human body completely as shown in Fig.14.Comparing with the method which Sekou Singare had proposed, this set of methods described in this study have four advantages.

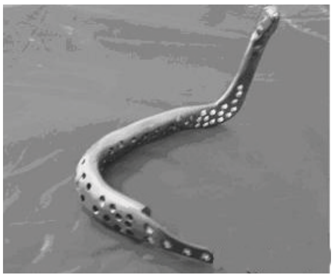

Figure 14. Titanium imported part

1) This set of methods were made up of kinds of professional software and largely reduced uncertain factors and errors which came from researcher's action. The researcher could build accurate outer contour and precise FEA, so the accuracy of model and the success rate of operation could be enhanced. This research is applicable to most of bone repair and large-scale promotion, so they have good business prospects.

2) Because the titanium implant was in the human body for a long time, the metal ions may leak and have a bad effect on human health [13]. Long-term use would also lead to increasing the internal stress and the rate of fatigue fracture. When the RIF was used, the titanium plate could be removed by the second operation after the mandible grew together with the fibula and the repaired mandibular could stand kinds of normal bite force.

3) After the FE model was established, the mechanical data would be analyzed to judge whether the model was qualified. It could decrease the risk of surgery, optimize the surgery program and alleviate the patient's suffering.

4) Autogenous bone graft has the capacity of becoming its marked osteogenic bone and resisting against infections.

This study represents a new approach for surgical planning and simulation, and both the designer and surgeon appreciate the meaning for comprehending the model. The mandible FE model has the ability to do the biomechanical analysis for the mandible model, and increase surgical precision over surgeries performed without the aid of mandible FE model. It should be recognized that there are a few shortcomings to improve such as: the intermediate links which were prone to lose some datum, higher operating skills which need higher knowledge to master, so it remains a big challenge and deserves the need for more attention and further research.

# A RFID mutual authentication protocol based on AES algorithm

Tuan Anh Pham, Mohammad S. Hasan and Hongnian Yu
Faculty of Computing, Engineering and Technology, Staffordshire University, Stafford, UK
tapham@live.com, {m.s.hasan, h.yu}@staffs.ac.uk

*Abstract*— **The emergence of RFID applications has huge influence to become pervasive in modern life. However the vulnerability of the transmission through the air and the unique identification number of RFID tag are the drawbacks that impact the popularity of RFID technology. In this paper, a mutual authentication protocol is proposed based on the challenge – response model. The Advanced Encryption Standard (AES) is used as a cryptographic primitive to secure the data. The experimental works are carried out to validate the protocol in term of security and privacy. The timing analysis is also presented and applied to a case study of conveyor belt system.**

***Keyword: RFID, AES algorithm, mutual authentication***

## I. Introduction

Recently Radio Frequency Identification (RFID) systems have been becoming popular and aiming to be ubiquitously applied in many areas including library, banking, logistics, transportation, manufacturing, supply chain system, military etc. Some large corporations who have deployed this technology are Wal-Mart, Procter and Gamble, and the United State Department of Defense [1] etc.

A RFID tag can be read as long as the item is within the range of the reader without requiring the line-of-sight operation as bar code technology. However, one of the biggest difficulties to the adoption of RFID technology is the lack of security and privacy. There is little security on the RFID tags or during the communication with reader which causes the RFID system vulnerable to many types of attacks e.g. information leakage, replay, denial of service [2], [3].

Many authentication protocols have been proposed to enhance the robustness of a RFID system. Some of them were developed based on cipher algorithms such as Advanced Encryption Standard (AES) or Elliptic Curve Cryptography (ECC) [4], [5], [6], [7]. Some utilised the hash-based algorithm, pseudo random number generator, Cyclic Redundancy Check (CRC) function and/or some ExOR and rotation operations [8], [9], [10], [11], [12]. Normally, cipher-based approaches are not preferred for passive tag because of its high computational cost and the large hardware area. However, with the advances in technology, it is feasible to embed the cipher engine on the passive tags but still guarantee the low tag's cost [5].

The aim of this paper is to develop a protocol to provide a strong, high security and trustful authentication scheme which can protect against most of well-known RFID system attacks. Thus, a novel mutual authentication protocol based on AES primitives and challenge – response method is proposed. The symmetric block cipher AES-128 is utilised in this proposal because it has been standardised and proved to be secure [13].

The rest of the paper is organised in six parts from section II to section VII. Section II briefly introduces the recent works. Section III proposes the novel protocol. In section IV, the analyses of the protocol in term of security and privacy are presented. Section V provides some experimental results. And section VI introduces a case study on conveyor belt system. The last section, section VII, is the conclusion of the paper.

## II. Related works

### A. *RFID security proposals*

There are the number of researches to address RFID security and privacy issues. This paper roughly categorises them into two categories: **cipher-based protocols** which are developed on AES or ECC algorithms and **hash-based protocols and others** which are based on hash functions and/or some simple operators such as ExOR, rotation etc.

#### 1) *Cipher-based proposals*

A strong authentication for RFID systems is introduced in [5] by implementing one-way encryption AES algorithm on RFID passive tag. A modified communication method between the reader and tag is also proposed in order to satisfy the strict timing requirement. However, this research reveals a possibility for the adversary to achieve the shared key of the AES encryption block [7]. In addition, the identical challenge always results in the identical cipher response which causes it to be susceptible to replay attack and tag clone. For example, assuming the challenge is the 16-bit output of Pseudo Random Number Generator [14], it is feasible for attackers to collect a database of 65536 entries to impersonate the legitimate devices to obtain the authentication.

Extending from the research of [5], [7] offers an advanced mutual authentication using the AES algorithm as a cryptographic primitive. The main issue of this protocol is easy to lose the synchronisation between the reader and the tag if the response from tag is blocked. Another security issue of this research is the man in the middle attack [6].

[4] develops a mutual authentication protocol based on Elliptic Curve Cryptography (ECC) which is an asymmetric

cryptographic algorithm. However, it is susceptible to DOS attack. The attackers can modify the counter value in the message sent from the server to the tag by a much larger value in order to deceive the tag into updating it. In next authentication, because the counter value in the tag is greater than the one the server sends, the tag terminates the authentication process right away.

### 2) *Hash-based proposals and others*

[11] proposed a mutual authentication protocol for passive tag which is based on cryptographic hash functions. A method to prevent the desynchronisation between a reader and a tag was proposed as well. This proposal however might disclose the issues of tracking, tag impersonation and the DOS attack [15].

Another hash-based two-way authentication scheme which employs Cyclic Redundancy Check (CRC) and Pseudo Random Number Generator (PRNG) function was presented in [9]. Although it was claimed to be robust, the attackers are still able to track the tag due to its identical response. Furthermore, the replay attack and tag impersonation can be carried out to compromise the valid reader. For example, the attackers possibly play on the response from the tag embedded in the cheap product and then replay that to the standard item.

[12] proposed a scheme for RFID system conforming to EPC Class 1 Generation 2 specifications. However, [16] has pointed out many security failures in this protocol. Moreover, the DOS attack can be employed to desynchronise the database server and the tag [10]. [16] has also indicated the possibility of auto-desynchronisation at backend database up to 0.93 if the population of tags is greater than $2^{18}$ tags.

To overcome the security issues of [12], [10] enhanced the scheme to defend against DOS attack, replay attack, forward secrecy and privacy concern. However, [17] and [8] claimed that this proposed protocol is not invulnerable due to the insufficient size of the secure keys. Consequently, it is susceptible to Tag/Reader impersonation attack and desynchronisation as [17] also claimed.

## III. THE PROPOSED PROTOCOL

### A. *Assumptions*

- A tag has the AES-128 encrypting block on-board proposed in [26].
- A reader and database server can perform AES-128 encryption and decryption.
- The channel between the reader and tag, the reader and backend database are vulnerable.

### B. *Initialisation phase*

At the beginning, the backend database, the reader and the tag have the same shared key *K*. The seed *s* of each tag is stored on the server and on the rewriteable memory of tag. The *ID* is placed in tag's read-only memory and server as well. In addition, the server and reader keep the reader identification number $ID_R$ for reader authentication purpose.

### C. *Authentication phase*

The authentication phase is illustrated in Figure 1.

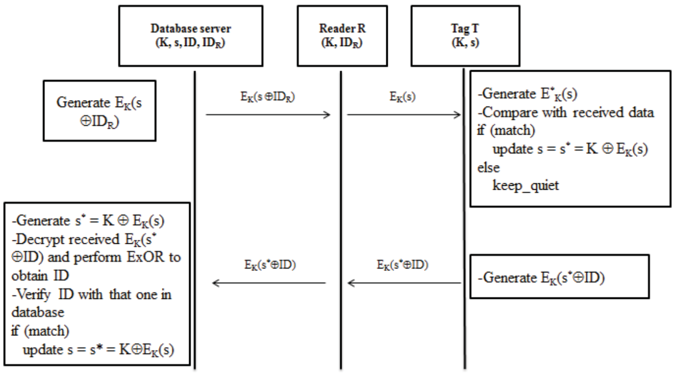

Figure 1. The proposed protocol

- Step 1: Query

Initially, the server generates $E_K(s⊕ID_R)$ and sends to the reader. The reader will decrypt this value to obtain the seed *s* by performing $s=ID_R⊕(ID_R⊕s)$. Afterward, reader encrypts the seed *s* and forward to the queried tag.

- Step2: Reader-to-Tag authentication

On receiving $E_K(s)$, the tag employs the on-board AES encrypting block to produce its own $E^*_K(s)$ and then check whether $E^*_K(s)=E_K(s)$ holds. If not, the tag keeps quiet. On the contrary, tag updates the seed *s* by $s^*=K⊕E_K(s)$ and again performs AES encrypting block to compute $E_K(s^*⊕ID)$ in order to convey to the reader.

- Step 3: Tag-to-Reader authentication

Upon obtaining $E_K(s^*⊕ID)$, the reader will pass it to the backend database to decrypt it. The decrypted value $s^*⊕ID$ is used to extract the tag's *ID* by carrying out the simple operation $ID = K⊕E_K(s⊕(s^*⊕ ID)$. Then this *ID* is verified by comparing with the *ID* existing in database to check whether this tag is legally acceptable or not. If the mismatch occurs, the server discards any data it has received and declines the authentication of the tag. Oppositely, the server updates the seed value of reader by $s^*=K⊕E_K(s)$ to guarantee the synchronisation of the system.

## IV. SECURITY AND PRIVACY ANALYSES

### A. *Information leakage*

Due to the insufficient protections and unreliable security levels, the data transmitted through the air are easily compromised. In this protocol, there are two messages interchanged between the reader and the tag. However, these sensitive data are encrypted by AES-128 cryptographic block. The attackers cannot get the plaintext or the raw data. So the information leakage is evitable.

### B. *Tag tracking and tracing*

For even EPC or IEEE standard, RFID tag is designed to have a unique number which can be tracked in range of any readers. However, this protocol provides the mechanism that whenever the counterfeit reader queries the tag, the tag does not send any response back. Consequently, the tracking and tracing privacy is secure in this protocol.

### *C. Tag clone*

In theory, there is no tag which has similar unique identifier number to another one. However, adversaries can replicate the forged tag without much effort and expense [18]. To conduct the tag clone attack, the attackers have to obtain the key $K$, seed $s$ and the $ID$ of the tag. However, these shared data are kept safely and privately in the backend database and inside the tag; the attackers have no information to perform the same encryption block to acquire the authentication.

### *D. Man-in-the-middleattack*

The adversative readers can impersonate the valid one in order to intercept, change and obtain the messages going between the parties which they need. In the proposed protocol, before querying the tag, the server sends the message $E_K(s \oplus ID_R)$ to the reader. Because only valid reader has the key $K$ to decrypt this cipher text, there is no possibility for attackers' readers to achieve the seed $s$ in order to communicate with the tag. Thus the man-in-the-middle attack can be avoided.

### *E. DOS(Denial of Service) attack*

It affects any wireless communication e.g. WiFi, RFID etc. by obstructing or intercepting the wireless signal that causes loss of synchronisation among the devices. Let us assume the scenario in which the response $E_K(s \oplus ID)$ is intercepted by the adversary. Because the reader has not got the response from the tag, it does not update its seed. In the next authentication, reader sends $E_K(s)$ to challenge the tag. But the seed in tag now is $s^* = K \oplus E_K(s)$, therefore, $E_K(s) = E_K(s^*)$ is not satisfied and the tag keeps quiet. So the solution is that reader will attempt with $E_K(K \oplus E_K(s))$. At this attempt, the synchronisation is re-established. Hence, the proposed protocol is insusceptible to DOS attack.

### *F. Replay attack*

In replay attack, the adversaries stand in the middle of communication channel to duplicate the valid transmission which will be fraudulently repeated later. However, the seed $s$ is automatically updated after each successful authentication session. This leads to the fact that the cipher text $E_K(s)$ changes in every authentication cycle. Thus, the attackers cannot utilise the former data in order to deceive the authorised reader or tag to overcome the authentication process.

Overall, the proposed protocol is able to protect against many types of the known attacks. The comparison with other researches is shown in Table I to have a general view of the robustness of this protocol.

## V. SIMULATION AND VALIDATION

The simulation is executed on a computer with Intel T3200 2GHz processor, 2GB of Ram memory on Windows 7 Ultimate. The C programming language has been used to develop the simulations. The AES core is the open source program designed by Niyaz PK [19].

### *A. Performance analysis*

In this proposed protocol, the messages transmitted on the channel are always encrypted. However, the adversaries can play brute-force attack (BFA) to attempt to get the answer from the tag. But since the size of the message is 128 bits, it is not feasible to perform BFA entirely with all the possible cases (more than $3x10^{38}$). Therefore, the simulation will randomly pick up an amount of random 128-bit input vectors (it is called sub-BFA) in order to verify the possibility of unintentional matches. The results are shown in Figure 2.

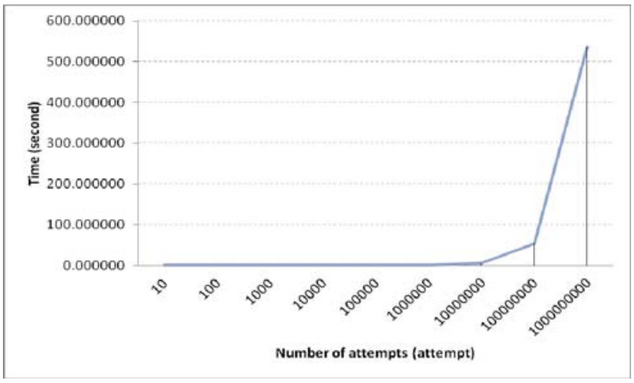

Figure 2 Time taken for sub brute force attack

Another simulation is conducted to measure the average time to perform one typical AES-128 encrypting operation. It is shown that it takes about **37µs** to complete.

From the simulation results, the protocol is robust to brute-force attack. And in case the server desynchronises, it takes just a few seconds to perform the AES encrypting computations to obtain the synchronisation.

### *B. Timing analysis*

#### *1) Timing components*

In this section, the minimum and maximum time requirements of the communication among the server, the reader and the tag are analysed. The time complexity is calculated based on the parameters in [14]. The timing model is shown in Figure 3.

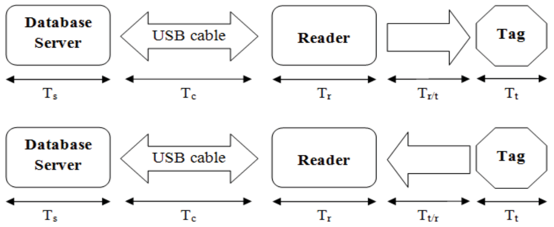

Figure 3. Timing model

In which:

$T_s$, $T_r$, $T_t$ : time for the database server, reader and tag to perform the AES algorithm respectively.

$T_c$ : time to transfer 128-bit message from the database to the reader through high-speed USB cable

$T_{r/t}$, $T_{t/r}$ : time to transmit 128-bit message from the reader to the tag and from the reader to the tag respectively.

The values of $T_s$, $T_r$, $T_t$ and $T_c$ can vary depending on the configuration of the server, reader, tag and the length of the cable, respectively.

#### *2) Assumptions*

- $T_s$, $T_r$, $T_t$ and $T_c$ are assumed to be constants.
- The computational times for AES encryption and decryption are the same.

#### *3) The minimum and maximum values*

Figure 4 shows the timing details of communication between the reader and the tag.

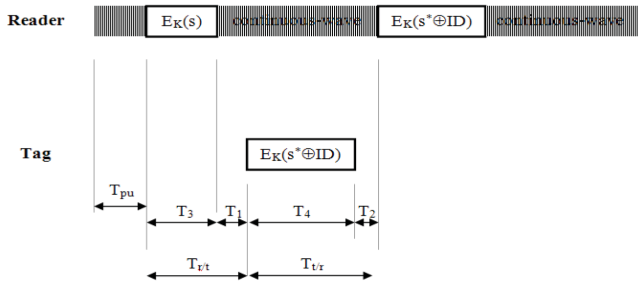

Figure 4. Time of reader & tag communication

In which:

$T_{pu}$ : time for tag to power-up

$T_1$, $T_2$ : time from reader transmission to tag response and from tag response to reader transmission respectively

$T_3$, $T_4$ : time to transmit 128-bit message from the reader to tag and from the tag to reader

Let T be the total time of an authentication cycle.

$$T = T_{\text{database}\to\text{tag}} + T_{\text{tag}\to\text{database}}$$

$$= (T_s + T_c + T_r + T_{r/t} + T_t) + (T_t + T_{t/r} + T_r + T_c + T_s) \qquad \textbf{(1)}$$

In tag-to-database direction, the value $T_r$ is 0 because the reader just transfers the tag's response to the database without performing any AES operation.

Therefore, (1) can be written as (2).

$$T = 2 \text{ x } (T_s + T_c + T_t) + T_r + (T_{pu} + T_1 + T_2 + T_3 + T_4) \qquad \textbf{(2)}$$

#### *4) $T_s$ & $T_r$*

The database requires one AES operation in either database-to-tag or tag-to-database authentication. According to section V.A, the time requirement to perform one AES encrypting function is about 37µs, therefore $T_s$ = 37µs.

The reader requires two AES operations on the way from the database to tag. Based on the assumptions presented in section V.B.2), $T_r$ can be presented by (3).

$$T_r = 2 \text{ x } 37 = 74\ \mu s \qquad \textbf{(3)}$$

#### *5) $T_t$*

The AES encrypting operation at the tag takes 356 clock cycles at the frequency of 100 KHz [20]. So $T_t$ is calculated as below.

$$T_t = 356 \text{ x } \frac{1}{100\times10^3} = 3560\mu s \qquad \textbf{(4)}$$

#### *6) $T_c$*

$T_c$ is computed by adding the time of transferring 128 bits from the server to the reader and the delay of the cable. Because the USB 2.0 can transfer at 480 Mbps and the cable delay is 26ηs [21]. So the value of $T_c$ is:

$$T_c = 128 \text{ x } \frac{1}{480\times10^6} + 26\eta s = 0.29267\mu s \qquad \textbf{(5)}$$

#### *7) $T_{pu}$*

[14] does not define the minimum of $T_{pu}$, it only indicates the maximal value of 1500µs for powering up the tag. Therefore, let us assume the min($T_{pu}$) = max($T_{pu}$) = 1500 µs.

#### *8) $T_1$*

[14] has given the equation to compute $T_1$ as (6).

$$\max(RTcal, 10T_{pri})x(1 - FT)\text{-}2\mu s \le T_1 \le \max(RTcal, 10T_{pri}) \qquad \textbf{(6)}$$

To calculate RTcal and $T_{pri}$, some values are given from [14] such as 6.25µs≤Tari≤25µs, 2.5Tari≤RTcal≤3.0Tari, 1.1RTcal≤TRcal≤3RTcal, BLF = $\frac{DR}{TRcal}$ , $T_{pri} = \frac{1}{BLF}$ .

Therefore, the minimum and maximum values for RTcal and TRcal can be expressed in (7).

$$\min(RTcal) = 15.625\mu s;\ \max(RTcal) = 75\mu s$$

$$\min(TRcal) = 17.1875\mu s;\ \max(TRcal) = 225\mu s \qquad \textbf{(7)}$$

Based on the minimum and maximum values of TRcal, the values of BLF and $T_{pri}$ can be found according to [14].

$$\max(BLF) = 465KHz;\ \min(BLF) = 95KHz$$

$$\min(T_{pri}) = \frac{1}{465\times10^3} = 2.15\mu s;\ FT = 19\% \qquad \textbf{(8)}$$

$$\max(T_{pri}) = \frac{1}{95\times10^3} = 10.53\mu s;\ FT = 5\%$$

Hence the minimum and maximum values of $T_1$ can be derived from (6) as (9) and (10), respectively.

$$\min(T_1) = \min(\max(RTcal,\ 10T_{pri}) \text{ x } (1 - FT) - 2\mu s) \quad \textbf{(9)}$$

$$= \max(\min(RTcal),\ 10 \text{ x } \min(T_{pri})) \text{ x } (1 - FT) - 2\mu s = 15.415\mu s$$

$$\max(T_1) = \max(\max(RTcal,\ 10T_{pri})) \quad \textbf{(10)}$$

$$= \max(\max(RTcal),\ 10 \text{ x } \max(T_{pri})) = 105.3\mu s$$

*9) $T_2$*

The equation used to calculate $T_2$ is referred from [14].

$$3T_{pri} \le T_2 \le 20T_{pri}$$

Therefore, the minimum and maximum values of $T_2$ can be computed as (11).

$$\min(T_2) = 3 \text{ x } \min(T_{pri}) = 6.45\mu s$$

$$\max(T_2) = 20 \text{ x } \max(T_{pri}) = 210.06\mu s \quad \textbf{(11)}$$

*10) $T_3$ & $T_4$*

In the reader-to-tag transmission, the reader starts signalling with either a preamble or a frame-sync as specified in [14]. This investigation assumes that the reader uses the frame sync which includes 3 components: delimiter=12.5µs; data-0=1Tari; RTcal [14]. The 128-bit data are sent afterward. At the end of the signalling either 2-bit 00 or 11 indicates the end of a communication. On the other hand, the tag starts the tag-to-reader signalling with a 6-bit preamble, then 128-bit data and 2-bit end of signalling.

The minimum and maximum values of $T_3$ are shown in (12) and (13) at the data rate of 465 KHz and 95 KHz respectively.

$$\min(T_3) = t_{delimiter} + \min(1Tari) + \min(RTcal) + \min t_{130\text{ bits}}$$

$$= 12.5 + 6.25 + 15.625 + \frac{130}{465 \times 10^3} \times 10^6 = 313.94\mu s \quad \textbf{(12)}$$

$$\max(T_3) = t_{delimiter} + \max(1Tari) + \max(RTcal) + \max t_{130\text{ bits}}$$

$$= 12.5 + 25 + 75 + \frac{130}{95 \times 10^3} \times 10^6 = 1480.92\mu s \quad \textbf{(13)}$$

Likewise, the minimum and maximum values of $T_4$ are computed as (14) and (15).

$$\min(T_4) = \min t_{136\text{ bits}} = \frac{6+128+2}{465\times10^3}\times10^6 = 292.47\mu s \quad \textbf{(14)}$$

$$\max(T_4) = \max t_{136\text{ bits}} = \frac{6+128+2}{95\times10^3}\times10^6 = 1431.58\mu s \quad \textbf{(15)}$$

Finally, deriving from (2) and the calculations above, the minimum and maximum values of T now can be resulted as (16) and (17).

$$\min(T) = 2 \text{ x } (T_s + T_c + T_t) + T_r + \min(T_{pu}) + \min(T_1) + \min(T_2) + \min(T_3) + \min(T_4) \approx 0.0094s \quad \textbf{(16)}$$

$$\max(T) = 2 \text{ x } (T_s + T_c + T_t) + T_r + \max(T_{pu}) + \max(T_1) + \max(T_2) + \max(T_3) + \max(T_4) \approx 0.012s \quad \textbf{(17)}$$

## VI. CASE STUDY: CONVEYOR BELT SYSTEM

The analysis and performance explained in section V.B are applied to estimate the maximum number of attempts for resynchronisation to a typical belt system as in Figure 5. The items with RFID tags are moving evenly from position A to position B on the conveyor belt. The range of the reader is L and θ is the angle covered by the antenna of the reader.

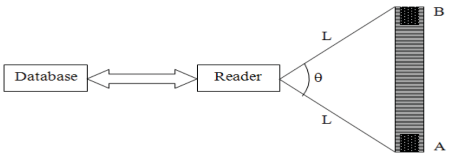

Figure 5. Model of RFID-based conveyor belt

The speed of the conveyor belt, $V_b$, is 2.5m/s which is the maximum speed in [22]. Hence, the time an item needs to move from A to B, denoted by t, is calculated as (18).

$$t = \frac{AB}{V_b} = \frac{2 \times L \times \sin\left(\frac{\theta}{2}\right)}{V_b} \quad \textbf{(18)}$$

[1] claimed that the read range varies from nominal range of 10cm to extended range of 50cm, so min(L) = 10cm and max(L) = 50cm. In addition, theoretically $0 \le \theta < 180$, it is inferred that $0 \le \sin\left(\frac{\theta}{2}\right) < 1$.

The maximum number of resynchronisation attempts, N is computed as (19) and (20) which are the best case scenario and worst case scenario respectively. These computations are based on (16), (17) and (18).

$$N = \text{floor}\left(\frac{t}{\min(T)}\right) = \text{floor}\left(\frac{L \times \sin\left(\frac{\theta}{2}\right)}{0.0094}\right) \quad \textbf{(19)}$$

$$N = \text{floor}\left(\frac{t}{\max(T)}\right) = \text{floor}\left(\frac{L \times \sin\left(\frac{\theta}{2}\right)}{0.012}\right) \quad \textbf{(20)}$$

Figure 6 and Figure 7 shows the value of N in (19) and (20) respectively with different values of L and θ.

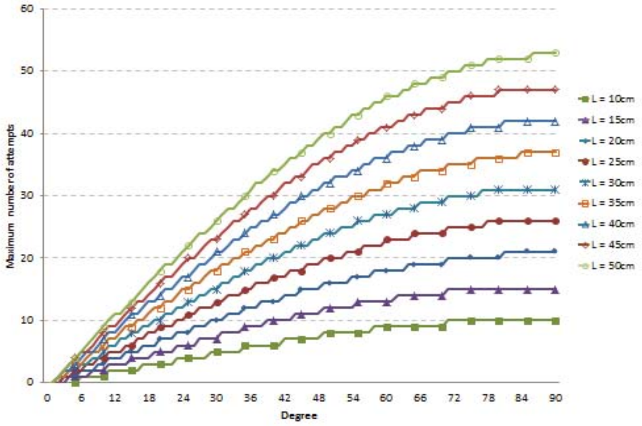

Figure 6. Maximum number of attempts to resynchronise a tag for various L and θ in case of min(T)

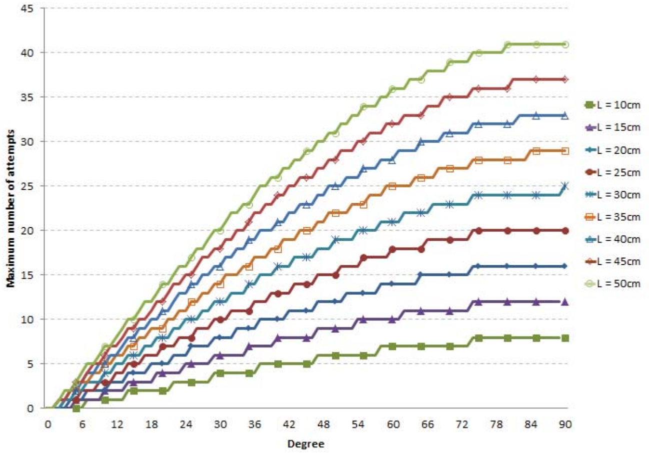

Figure 7. Maximum number of attempts to resynchronise a tag for various L and θ in case of max(T)

If θ = 68° is chosen as a reliable read angle as mentioned in [23], the values of N for min(L) = 10cm and max(L) = 50cm, are 6 and 29, respectively for the best case scenario or min(T). On the other hand, for the worst case scenario or max(T), the values are 4 and 23, respectively.

## VII. Conclusion

The proposed protocol in this paper is a mutual authentication protocol which utilises AES-128 as a primitive to encrypt the messages transmitted on the channel. With that cipher block, the protocol can protect against many types of attacks such as information leakage, tag tracking etc. In addition, the secure keys stored in tag and sever are always updated in each authentication session, it is impossible for attackers to play the replay attack or trace back the previous data.

*Abstract*—**In the non-destructive testing of materials, the use of imagery allows for more than only a qualitative representation of the results. Imagery can aid in automatically carrying out operations of detection, location and sizing of defects present in a structure. The rapidity of the calculators and their graphic performance allow us to use classical tools of image processing today, even though they require a large number of calculations. This work consists of applying the Hough transform to detect inclusions in a material by analyzing an ultrasonic c-scan image. In the first step, this image is binarized using the –6dB method, which reduces the defects to their real sizes. The Hough transform is then applied to the edges to detect the circular forms that characterize the inclusions.**

***Keywords-Non Destructive Testing; Ultrasonics; Imagery; Pattern Recognition.***

## I. Introduction

In non-destructive testing (NDT) of materials, the automatic characterisation of defects allows for faster decision making [1]. With the appearance of computing systems that are able to process recorded signals rapidly and create images, the possibilities of ultrasonic imagery in NDT improve steadily [2,3,4,5]. In addition to aiding in the control and decision-making processes, automation allows for control under dangerous conditions of high-level radiation or in some industrial processes with low or null visibility due to the environment.

The Hough transform is a classical tool for pattern recognition [6]. It allows for the detection of parameterized forms, such as lines, circles, parabolas, etc. Because it requires a large number of calculations, it had been abandoned for ultrasonic imagery applications since its initial development in 1962 by Paul Hough. However, its robustness and its capacity to detect even incomplete edges keep it on the list of the most interesting tools for pattern recognition.

In precedent works, we have used Hough transform to detect cracks defects by analyzing another type of ultrasonic images, called TOFD (Time Of Flight Diffraction). In this case, sets of parabolas appear on the image and their recognition allows the crack detection [7].

This paper describes how the Hough transform can be used on an ultrasonic image produced by non-destructive testing to detect inclusions characterised by circular forms.

The c-scan image used here displays ultrasonic waves reflected by the defect at each position of a transducer moving on the structure. In Section 2, the synthesis of this type of image is described. The application of the –6dB method to the objects detected to reduce them to their real sizes is explained in Section 3 [8]. This operation also allows us to transform the image into a binarized one. Section 4 describes how the Hough transform can be applied to detect and locate circular forms corresponding to inclusions.

## II. IMAGE FORMATION

An automatic scanning system was used to move an ultrasonic focused probe step by step on a rectangular surface of the structure in a controlled manner.

At each position, an ultrasonic signal was emitted, and the reflected signal was detected and stored [9,10].

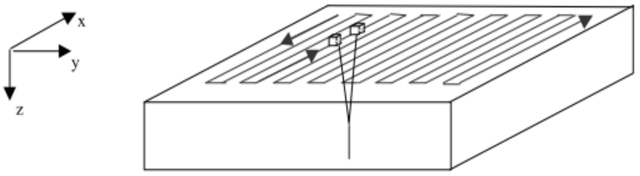

Figure 1. Displacements of the probe.

Figure 2 shows an example of the reached signal. Where appear the defect signal between surface echo and the backwall one.

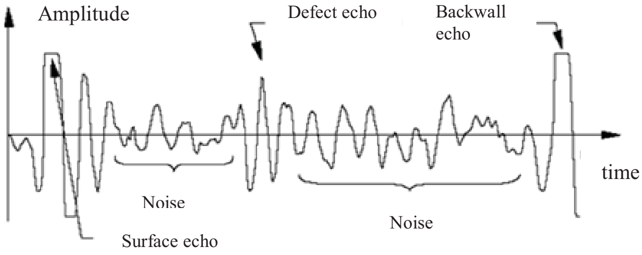

Figure 2. Example of a reflected signal.

The maximum amplitude of the echo corresponds to the value of the pixel at the corresponding coordinates of the probe. Figure 3 shows the results obtained by scanning a square area on the structure.

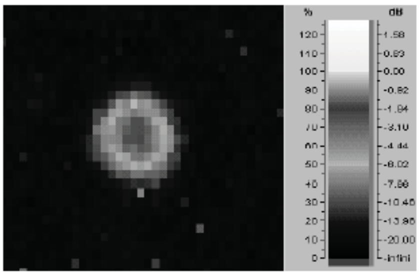

Figure 3. C-scan image containing a circular defect.

To detect small inclusions, the probes must be focused. The image used in this work was formed with measurements taken with focused transducers of 5 MHz on a Ti-Al part with steel inclusions (Figure 4).

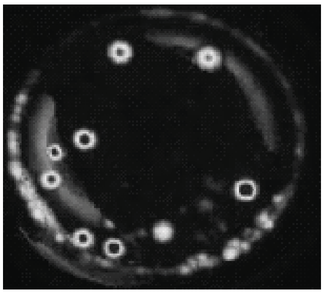

Figure 4. C-scan on a Ti-Al part with steel  inclusion.

To reduce the objects in the c-scan image to their real sizes, we must take into account the surface of the ultrasonic beam. Figure 5 illustrates the principle behind the –6dB method. The probe is moved along the defect, and the distance over which the signal amplitude is above half of the maximum corresponds to the length of the defect.

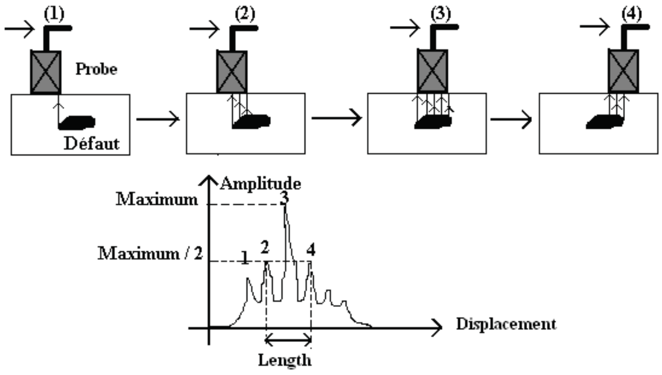

Figure 5. -6dB method for sizing defects.

Applying this method to the image in Figure 4 results in cancelling all the pixels for which the value is lower than half of the maximum signal. The remaining pixels take the value 1 to produce a binary image (Figure 6 (a)). The edges of the defects, which are sufficient for the application of the Hough transform, are then extracted, as shown in Figure 6 (b).

## III. THE HOUGH TRANSFORM

### *A. Principle of the Hough Transform*

The Hough transform was initially developed for the detection of points aligned on a straight line. More generally, it can detect more complex shapes as long as we know how to define a mathematical model for these shapes. The Hough transform consists of considering all the possible positions and orientations of the shape (for example, all the possible values for the parameters, a and b, of a straight line defined by the equation, y = ax + b, in the x-y plane). Then, for each position and orientation (defined by a particular value of the parameters, a and b), the number of contributing points in the source image is counted. In the decision step, all straight lines defined by the parameters (a,b) such that the number of contributing points in the source image is greater than a threshold are determined.

### *B. Circle Hough Transform*

The Hough transform can be used to determine the parameters of a circle when the number of points that fall on the perimeter are known [11]. A circle with radius r and center (a,b) can be described by the following parametric equations:

$$x = a + r\cos(\theta) \qquad (1)$$

$$y = b + r\sin(\theta) \qquad (2)$$

When the angle θ sweeps through 360 degrees, the points (x,y) trace the perimeter of a circle.

If an image contains many points, some of which fall on perimeters of circles, then the job of the search program is to find parameter triplets (a,b,r) to describe each circle. The fact that the parameter space is 3D makes a direct implementation of the Hough technique more expensive in terms of both computer memory and time. In this work, a graph partitioning separates different populations of pixels [12]. Applied separately on each partition, the Hough transform in this case needs only to detect the co-ordinates (a,b) of the center; the radius is then calculated by taking into account the perimeter of the object .

### *C. Application of the Hough Transforms*

For each pixel $(x_i,y_i)$ of a given population of pixels, the Hough transform associates a circle in the Hough space with the co-ordinates $(x_i,y_i)$. The radius was calculated previously using the length of the edges; the radius is the perimeter divided by 2π.

At the same time, the intersections of the circles are counted in an accumulator, and one is added for each cell crossed.

At the end of this process, the Hough space is analyzed by looking for the points with the maximum number of intersections. Relatives maxima correspond to the circles detected.

## IV. RESULTS

Applied to the image of the edges, as shown in Figure 6, the Hough accumulator is obtained, as shown in Figure 7.

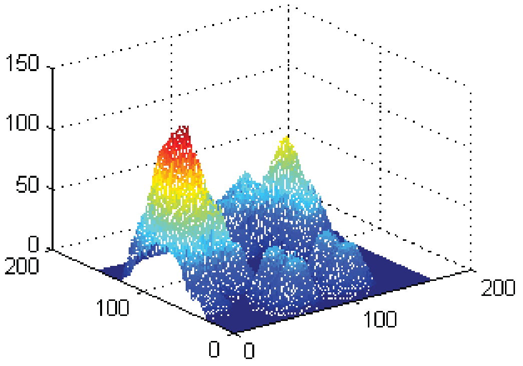

Figure 7. Hough accumulator.

The decision must take into account the highest value cell, which corresponds to the biggest inclusion. Thus, the lowest peaks are eliminated, depending on the precision needed. For this example, a threshold equal to half of the maximum peak was chosen. After detecting the coordinates of the other relative maxima, the corresponding circles were presented on the same image (Figure 8).

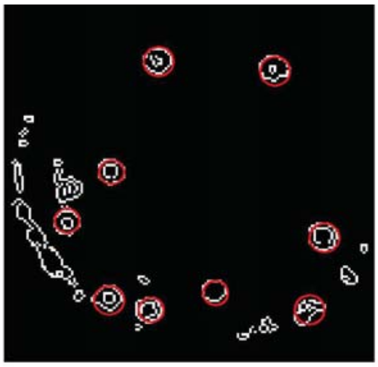

Figure 8. Detected inclusions.

## V. CONCLUSION

In this work, the Hough Transform, a classical tool for pattern recognition, was applied to automatically detect inclusions in a structure, which are characterized by their circular forms.

Graph partitioning, which involves separating different populations of pixels, allowed us to leave the radius out of the parameters to consider. With a reduction to two parameters (the coordinates of the centre), the Hough space shows most of circles corresponding to inclusions. The overall result is promising.

# System Identification and Robust Anti-windup Control for a Helium Liquifier

Jing Na, Guang Li, Ryuji Maekawa and Luigi Serio

*Abstract*— **This paper addresses the system identification and advanced control of a helium (He) liquifier supplying cooling power at liquid helium (LHe) temperatures (-269 °C). To study the dynamic response to heat load variation, a He liquifier simulation model is utilized. The main focus is to regulate the discharge pressure of the compressor station to guarantee stable system operation. System identification is first conducted to obtain plant models, and a two degree of freedom $H_\infty$ controller is designed to achieve regulation. Moreover, saturation of the control valve is compensated via an anti-windup technique, which is suitable for regulation problem with disturbance rejection. The effectiveness of the proposed control designs is demonstrated by dynamical simulations in EcosimPro (*EA International*) software.**

*Index Terms*— **Helium liquefier, anti-windup, robust control, disturbance rejection.**

## I. Introduction

ITER [1] that is now under construction at Cadarache, South of France is designed to demonstrate the scientific and technical feasibility of nuclear fusion as a primary source of virtually inexhaustible energy. It is the biggest fusion energy research project, and one of the most challenging and innovative scientific endeavors in the world today [2]. The machine requires high magnetic fields to confine and stabilize the plasma. For such a facility, a cryogenic system will be employed to cool-down and maintain the superconductivity state of the magnets. The ITER cryogenic system [3], [4] will be one of the largest cryogenic systems in the world with a refrigeration capacity of 65 kW equivalent at 4.5 Kelvin.

In cryogenic systems, various components (e.g. heat exchangers, valves, turbines, compressors, etc.) are employed, and the associated controllers are required. To facilitate the control design, several dynamic simulators have been developed, e.g. C-PREST for LHD [5], PROCOS for LHC [6], [7]. Based on dynamic simulators, some advanced control methods have also been presented, for example, internal model control (IMC) [8], nonlinear model predictive control (MPC) [9] and other methods [10], [11]. In these schemes, the discharge pressure of the compressor station (CS) is regulated to guarantee the stable system operation. In [8] and [10], system identification method is also utilized. However, the modeling uncertainties are not explicitly considered in the control design and the potential control valve saturation is not studied.

To address the aforementioned issues, this paper proposes an alternative system identification and advanced control design method. A helium liquefier simulation model originally designed in [12] is employed as the plant to be controlled. However, to facilitate the control design, modifications on the CS control configuration have been done (will be explained in Section II). Moreover, to study the dynamic response of the liquefier, time-varying heat loads are applied in the reservoir. The major focus of this study is to regulate the discharge pressure of CS under dynamic heat loads to sustain the system stability.

The frequency-domain system identification is conducted to obtain the mathematical models, which are supposed to cover system dynamics in a wide frequency band compared to those models from the time-domain identification. Then a $H_\infty$ robust controller [13], [14] is designed to accommodate the modeling uncertainties. Moreover, to recover the control performance in the presence of the control valve saturation, a robust disturbance rejection anti-windup framework (DRAW) recently developed in [15] is employed. The salient feature is that the modeling uncertainties and the disturbance rejection can be incorporated into the AW compensator design and synthesis. Simulation results in a commercial software, EcosimPro [16], are provided to illustrate the performance improvement over alternative approaches. Hence the main contribution of this paper is to provide a systematic robust anti-windup control design procedure for CS pressure regulation of He liquifier with dynamic heat loads, based on frequency system identification and advanced control strategies.

## II. Helium liquifier

Commercial modeling and simulation software, EcosimPro [16], has recently been used for cryogenic simulations. With this software, a cyo-library has been developed by researchers [6], [7], [8] at the European Organization for Nuclear Research (CERN). In this library, various cryogenic component models are constructed based on the mass flowrate and energy balance and the helium properties are obtained from the helium library HEPAK [17].

### A. Helium liquefier model

A helium liquefier designed by CERN [12] is adopted in this study. The liquefier consists of a warm compressor station (CS) and a cold-box (CB) including two expansion turbines (TU), four heat exchangers (HX), a LHe reservoir and connecting pipes and valves. The overall process and instrument diagram (P &ID) is depicted in Fig.1. The CS model and CB model and their associated control structure simulated in EcosimPro are shown in Fig.2 and Fig.3. The entire model contains 1799 differential and algebraic equations (DAEs) with 157 derivatives, 21 boundary variables and 10 control loops.

978-1-4673-1560-9/12/$31.00 ©2012 IEEE

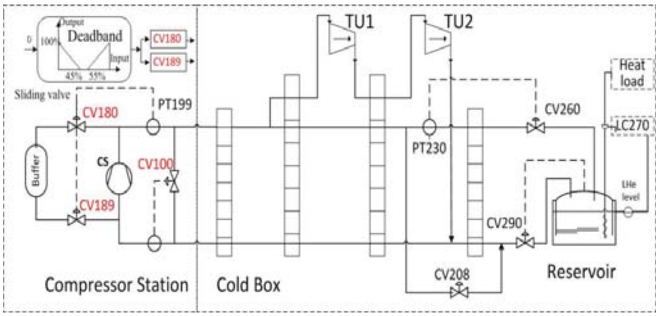

Fig. 1. P&ID of cryogenic system.

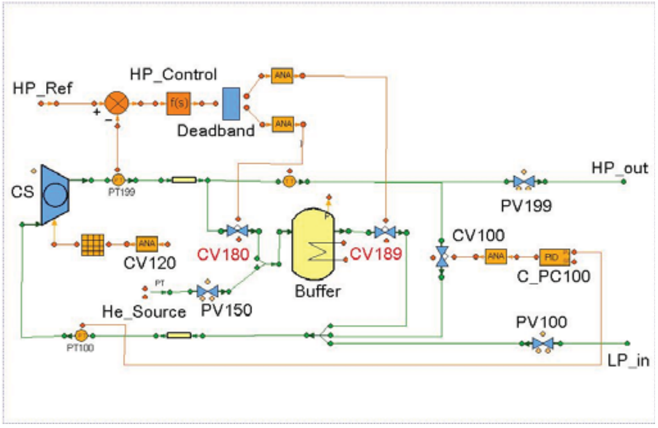

Fig. 2. Compressor station model.

The compressor station compresses helium from 0.1 MPa to 1.3 MPa providing mass flowrate 100 g/s. The discharge pressure or high pressure (HP) is regulated by two antagonist valves: the discharge valve (CV180) that removes the high pressure He into the buffer and a charge valve (CV189) that charges the low pressure from the buffer. It should be pointed out that in the original model proposed in [12], two separated PI controllers with different setpoints are utilized for valves CV180 and CV189. However, in this study the control configuration of CV180 and CV189 is modified to reduce the complexity of control design and to improve the performance. As shown in the left top of Fig.1, the HP is regulated by controlling a split-range valve with a deadband between MV=45%-55%, where the deadband takes the controller output as the input and the corresponding stem positions of the discharge valve CV180 and charge valve CV189 as the outputs. In this case, only one controller (i.e. HP_Control in Fig.2) is required for operating the valves CV180 and CV189 simultaneously. Moreover, the low pressure (LP) is regulated by a bypass valve CV100 connecting HP and LP.

In the cold-box (Fig.3), the inlet valves of turbines (TU1, TU2) are controlled based on their input pressures and the output temperatures. The Joule-Thomson (J-T) valve is controlled taking the inlet pressure as the control variable. The LHe level in the reservoir is regulated by means of an embedded electrical heater with a PI control.

### B. Control problem formulation

To simulate the dynamic response of the liquifier (as shown in Fig.1), the time-varying heat loads are directly applied in the reservoir [10]. In this case, the pressure fluctuations caused by the LHe evaporation (due to the heat loads) may deteriorate the system stability or even trigger instability (e.g. turbine trips) in the worst case. To sustain system stability and the LHe product, as explained in [11], several conditions should be guaranteed: 1) the HP and LP need to be regulated at the *a prior* designed constants (or within fixed intervals) to ensure the reliability of compressor; 2) the LHe level in the reservoir has to stay within an acceptable level to avoid drying or overflow.

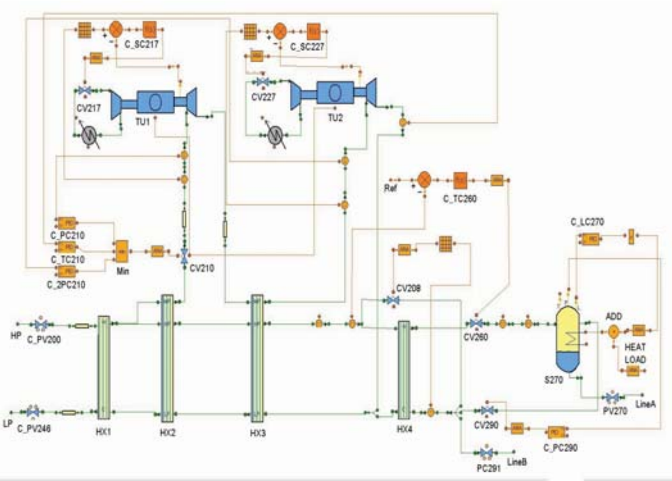

Fig. 3. Cold-box model.

To fulfil the requirement 1), we propose an alternative control design strategy for the liquifier (Fig.1) to regulate the HP of CS under dynamic heat loads. In particular, the control valve saturation is considered via an anit-windup (AW) compensator. Other control loops in the cold box are operated with PI controls guaranteeing also condition 2).

## III. Plant Model Identification

As shown in Fig.1, the HP regulation can be achieved by controlling the sliding valve (CV180/CV189). The heat load applied in the LHe reservoir is taken as the disturbance $d(t)$, the HP of CS is taken as the output $y(t)$, and the position of sliding valve (CV180/CV189) is taken as the input $u(t)$ which is constrained within $[0,100]$ (i.e. valves should be opened between 0% - 100%). Then the overall system dynamics can be described as

$$Y(s) = G_u(s)U(s) + G_d(s)D(s) \qquad (1)$$

where $Y(s), U(s)$ and $D(s)$ are the Laplace transform of $y(t), u(t)$ and $d(t)$, respectively. The transfer function $G_u$ denotes the dynamics from the control input $u$ to output $y$ and $G_d$ denotes the dynamics from the disturbance $d$ to output $y$.

Note there are some nonlinearities (e.g. deadband) in the system (Fig.1). For ease of system identification and control design, linear transfer function (1) is used to represent the main system dynamics and the modeling uncertainties will be considered in the control design in terms of robust control scheme. To obtain models $G_u(s)$ and $G_d(s)$ under wide operation conditions, a frequency identification method based on the correction analysis [18] is adopted. The identification procedure is briefly summarized as follows:

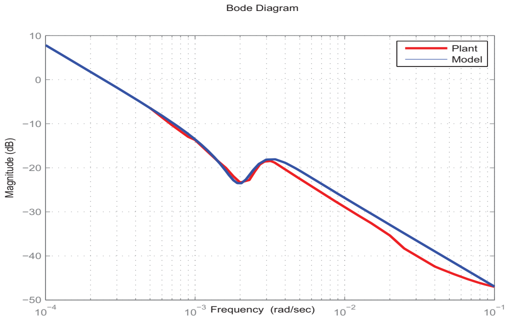

Fig. 4. Process model $G_u(s)$ (2) validation.

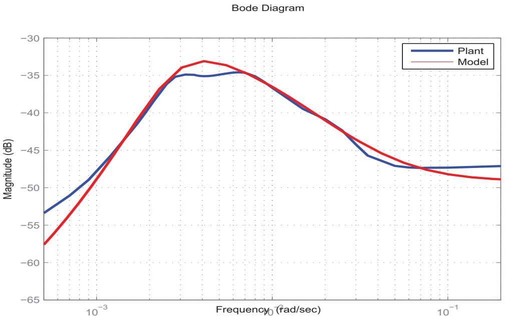

Fig. 5. Disturbance model $G_d(s)$ (3) validation.

1) Apply sinusoidal signals $u(t) = a_1 + b_1 sin(\omega t)$ as the system input and/or $d(t) = a_2 + b_2 sin(\omega t)$ as the disturbance with $a_i > 0, b_i > 0$, and then record the output $y(t)$;

2) Conduct the correlation analysis for data set $(u(t), y(t)), t \in [0, T]$ to deduce the auto-correlation functions $R_u(\omega)$, $R_d(\omega)$, $R_y(\omega)$ and cross-correlation functions $R_{uy}(\omega)$, $R_{dy}(\omega)$. Then calculate the magnitude $H_u(\omega)$, $H_d(\omega)$ and phase $\phi_u(\omega)$, $\phi_d(\omega)$ corresponding to frequency $\omega$ by using $R_u(\omega)$, $R_d(\omega)$, $R_y(\omega)$ and $R_{uy}(\omega)$, $R_{dy}(\omega)$.

3) Change the frequency $\omega$, and repeat calculations 2) for a number of frequencies in the studied frequency band.

4) Plot the magnitude and phase responses $\phi_i(\omega), H_i(\omega), i = u, d$ versus frequency $\omega$.

5) Derive the mathematical models from the plotted Bode diagrams via the curve fitting method.

In this study, the signal $u(t) = 51 + 10sin(\omega t)$ with $\omega$=0.0005∼0.8 rad/s is used as the input and $d(t) = 200 + 80sin(\omega t)$ Watt with $\omega$=0.0001∼0.3 rad/s is employed as the disturbance. 45 group of data sets for $(u(t), y(t))$ and 37 group of data sets for $(d(t), y(t))$ are recorded. Then following the above identification steps, we can derive the process model as

$$G_u(s) = K_u \frac{(s^2 + 2\xi_1 \omega_{n1} s + \omega_{n1}^2)}{s(s^2 + 2\xi_2 \omega_{n2} s + \omega_{n2}^2)} \tag{2}$$

with $\xi_1 = 0.2$, $\omega_{n1} = 0.002$, $\xi_2 = 0.4$, $\omega_{n2} = 0.0027$, $K_u = 4.5 \times 10^{-4}$, and the disturbance model as

$$G_d(s) = K_d \frac{s(1 + \frac{1}{T_1 s})(1 + \frac{1}{T_2 s})}{(s^2 + 2\xi \omega_n s + \omega_n^2)(1 + \frac{1}{1 + T_3 s})} \tag{3}$$

with $K_d = 1.995 \times 10^{-5}$, $T_1 = 0.0008$ ,$T_2 = 0.05$, $T_3 = 0.007$, $\xi = 0.6$, $\omega_n = 0.003$.

For comparison, Fig.4 and Fig.5 provide the magnitude responses versus frequency of process model (2) and disturbance model (3). It is shown that the derived models can capture main dynamics of the liquifier among the studied frequency band, which illustrates the validity of the proposed identification results.

## IV. $H_\infty$ CONTROL AND ANTI-WINDUP COMPENSATION

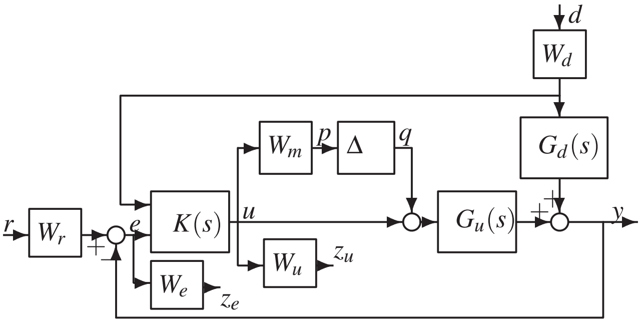

Fig. 6. Block diagram of the $H_\infty$ control for liquifier

In practice, there are usually unavoidable modeling uncertainties based on process model (2) and disturbance model (3) (as shown in Fig. 4 and Fig. 5). To accommodate unmodeled dynamics, $H_\infty$ synthesis method [13], [14] is used to design a 2-degree-of-freedom (DOF) controller $K(s)$. Moreover, since the sliding valve (CV180/CV189) can only be opened between 0-100%, an anti-windup compensator [15] is further incorporated to compensate for the valve saturation.

### A. $H_\infty$ controller design

The scheme for $H_\infty$ controller design of the liquifier is illustrated in Fig. 6. In this case, the plant model is supposed to be an input-multiplicative uncertainty model

$$\tilde{G}_u(s) = G_u(s)(1 + W_m(s)\Delta(s)), \tag{4}$$

where the uncertainty $\|\Delta(s)\|_\infty \leq 1$ and $W_m(s)$ is a weighting function. This uncertainty represents unmodeled dynamics from the control input to output (e.g. difference between the blue line and red line in Fig. 4). The uncertainties from the disturbance to output is not considered in $H_\infty$ controller design, since this uncertainty does not influence the robust stability of the feedback control system. A 2-DOF controller $K(s) = [K_d(s), K_e(s)]$ is designed, where $K_d(s)$ is the feedforward controller and $K_e(s)$ is the feedback controller. The controller $K(s)$ aims to minimize the mapping from $w = [d, r]^T$ to $z = [z_e, z_u]$, represented by $\mathscr{T}_{zw}$. In Fig. 6, the following relations hold

$$\begin{aligned} y &= G_u q + G_d W_d d + G_u u, && \\ u &= K_d d + K_e e, & e &= W_r r - y, \\ z_e &= W_e e, & z_u &= W_u u, \\ p &= W_m u, & q &= \Delta p. \end{aligned}$$

From the above relations, we can derive the following equation for $H_\infty$ control synthesis

$$\left[\begin{array}{c} p \\ \hline z_e \\ z_u \\ \hline d \\ e \end{array}\right] = \left[\begin{array}{cccc} 0 & 0 & 0 & W_m \\ -W_e G_u & -W_e G_d W_d & W_e W_r & -W_e G_u \\ 0 & 0 & 0 & W_u \\ 0 & W_d & 0 & 0 \\ -G_u & -G_d W_d & W_r & -G_u \end{array}\right] \left[\begin{array}{c} q \\ \hline d \\ r \\ \hline u \end{array}\right] \tag{5}$$

Here the uncertainty weighting function is chosen as $W_m = \frac{2s+0.05}{s+1}$, which represents an increase of unmodelled uncertainties from 5% at low frequency to 200% above 1 rad/s. The tracking performance weighting function is $W_e = \frac{0.25(s+0.4)}{s+2\times 10^{-5}}$. The input weighting function is $W_u = \frac{20(s+0.025)}{s+1}$; the magnitude of the weight increases above 0.025 rad/s to limit the closed-loop bandwidth. Those weighting functions should be chosen as a tradeoff between the tracking performance and input magnitude. The disturbance weighting function is chosen as $W_d = \frac{s+1}{s+0.005}$ to describe the high amplitude of the disturbance below 0.005 rad/s. The reference weighting function is $W_r = 1$. Using these weighting functions, an $H_\infty$ controller is synthesized using the commercial routine `hinfsyn` in robust control toolbox of MATLAB®.

### B. Anti-windup (AW) compensator design

In order to recover the performance during the control valve saturation (due to the valve hardware constraints), a separate AW compensator is needed [19], [20]. The AW compensator only provides compensation for the control signal when saturation occurs. In this paper, the AW approach recently proposed in [15] is adopted, which can explicitly incorporate the plant uncertainties and disturbance rejection into synthesis, and thus can make a tradeoff between the robustness and performance. The AW approach proposed in [15] is based on the framework shown in Fig. 7. It is assumed that the model has an additive uncertainty $\Delta_a$ which is related to (4) by

$$W_a = G_u W_m \tag{6}$$

The plant is $G = [G_d, G_u + W_a\Delta]$ and the controller $K$ is the $H_\infty$ controller designed in the last section. Suppose the right co-prime factorization of $G_u(s)$ is $N(s)M^{-1}(s)$, then the AW compensator takes the form of

$$\begin{bmatrix} M(s)E - I \\ N(s) \end{bmatrix} \sim \left[\begin{array}{c|c} A_p + B_pF & B_pE \\ \hline F & E - I \\ C_p + D_pF & D_pE \end{array}\right] \tag{7}$$

Here $G_u \sim (A_p, B_p, C_p, D_p)$ with $A_p \in \mathbb{R}^{n_p \times n_p}$. $F \in \mathbb{R}^{1\times n_p}$ and $E \in \mathbb{R}$ are the variables to be designed by the AW synthesis approach. The input of the AW compensator is the difference between the input and output signals of the saturation operator, and the AW compensator provides two compensation signals, which are added to the input and output signals of the feedback controller. The essential concept of this AW approach to minimize the $\mathscr{L}_2$ gain of

$$\frac{1}{\gamma_d}\left\| \begin{matrix} W_y^{\frac{1}{2}} y_d \\ W_r^{\frac{1}{2}} u \end{matrix} \right\|^2 - \gamma_d \|d\|^2 \leq 0 \tag{8}$$

while incorporating the saturation nonlinearity into synthesis. In (8), the $\mathscr{L}_2$ gains of the mapping from the disturbance $d$ to $y_d$ and the mapping from $d$ to $u$ should be minimized simultaneously. The mapping from $d$ to $y_d$ reflects the performance: a smaller $y_d$ can bring a better performance; the mapping from $d$ to $u$ reflects the robustness: a smaller $u$ leads to a larger margin for robustness. $W_y$ and $W_r$ are weighting matrices, which are positive diagonal and used to tradeoff the gains of the two mappings.

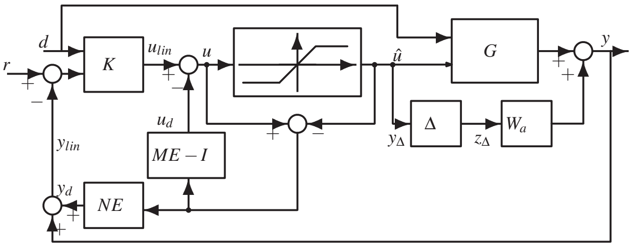

Fig. 7. Anti-windup framework with additive uncertainty

For completeness, the main steps for this AW compensation synthesis procedure is presented (see [15] for more theoretical background and [21] for a real application case.)

1) Compute a disturbance filter

$$P_d := (I - K_y G_u)^{-1}([K_d, w_d] + K_e[G_d, 0])$$

whose state space realization is $(A_d, B_d, C_d, D_d)$ with $A_d \in \mathbb{R}^{n_d \times n_d}$.

2) Given the matrix variable $P = P^T > 0$, solve $\gamma_d^* := \min \gamma_d > 0$ subject to LMI-1 in (9) and LMI-2 in (10) to yield $P^*$ and $\gamma_d^*$.

$$\mathbf{LMI-1}: \quad \begin{bmatrix} PA_o + A_o^T P + PW_A + W_A^T P & W_C + PW_B \\ W_C^T + W_B^T P & W_D \end{bmatrix} < 0 \tag{9}$$

with

$$A_o = \begin{bmatrix} A_p & 0 \\ 0 & A_d \end{bmatrix} \qquad W_A = \begin{bmatrix} 0 & B_pC_d \\ 0 & 0 \end{bmatrix}$$

$$W_B = \begin{bmatrix} B_pD_d & 0 & -B_p \\ B_d & 0 & 0 \end{bmatrix} \qquad W_C = \begin{bmatrix} 0 & C_p^T & 0 \\ 0 & C_{\tilde{d}}^T D_p^T & 0 \end{bmatrix}$$

$$W_D = \begin{bmatrix} -\gamma_d I_{n_w} & D_d^T D_p^T & 0 \\ D_pD_d & -\gamma_d I_{n_y} W_y^{-1} & -D_p \\ 0 & -D_p^T & -\Gamma \end{bmatrix}$$

and

$$\mathbf{LMI-2}: \quad \begin{bmatrix} A_d^T P_{22} + P_{22}A_d & P_{22}B_d & C_d^T \\ B_d^T P_{22} & -\gamma_d I_{n_w} & D_d^T \\ C_d & D_d & -\gamma_d W_r^{-1} \end{bmatrix} < 0 \tag{10}$$

Here the variables are the scalar $\gamma_d > 0$, diagonal matrix $\Gamma = \text{diag}(\gamma_1, \ldots, \gamma_{n_u}) > 0$, and $P$ is a symmetric positive definite matrix with a structure

$$P := \begin{bmatrix} P_{11} & P_{12} \\ P_{12}^T & P_{22} \end{bmatrix} \in \mathbb{R}^{n_p + n_d} \tag{11}$$

3) Substituting $P^*$ and $\gamma_d^*$ with some chosen diagonal positive definite $W$, solve the LMI:

$$\Psi + H^T \Lambda G + G^T \Lambda^T H < 0 \tag{12}$$

for $\Lambda$, with $\Lambda := \begin{bmatrix} F & E \end{bmatrix}$ and

$$\Psi = \begin{bmatrix} A_o^T P + PA_o & PB_o + C_{do}^T \tilde{W} & C_{po}^T \\ B_o^T P + \tilde{W} C_{do} & \tilde{W} D_{do} + D_{do}^T \tilde{W} - \gamma_d \tilde{I}_{n_w} & 0 \\ C_{po} & 0 & -\gamma_d I_{n_y} \end{bmatrix},$$

$$H = \left[\begin{array}{cc|cc|c} B_p^T & 0 & -1 & 0 & D_p^T \end{array}\right] \text{diag}(P, \tilde{W}, I),$$

$$G = \left[\begin{array}{cc|cc|c} I_{n_p} & 0 & 0 & 0_{n_p\times 1} & 0 \\ 0 & 0 & 1 & 0 & 0 \end{array}\right],$$

where $\tilde{W} = \begin{bmatrix} W & 0 \\ 0 & 1 \end{bmatrix}$, and

$$B_o = \begin{bmatrix} 0_{n_p\times 1} & 0_{n_p\times 1} \\ 0_{n_d\times 1} & B_d \end{bmatrix} \qquad C_{do} = \begin{bmatrix} 0_{1\times n_p} & C_d \\ 0_{1\times n_p} & 0 \end{bmatrix}$$

$$D_{do} = \begin{bmatrix} 0 & D_d \\ 0 & 0 \end{bmatrix} \qquad C_{po} = \begin{bmatrix} C_p & 0 \end{bmatrix}$$

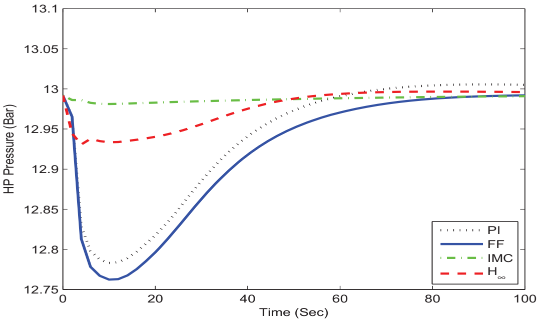

Fig. 9. HP regulation transient performance.

Note that the possible algebraic loop issue (in case $E \neq 1$) can be resolved using the idea as in [15].

## V. Simulation and Discussion

### A. Simulation in EcosimPro

To verify the proposed control method, real-time simulation results in the software EcosimPro are given. Several cases are simulated:

- **Time-varying disturbance**: The simulation is first conducted with a time-varying heat load $d(t) = 80\sin(0.005t) + 200$ applied in the reservoir. Several control methods, PI control (PI), feedforward control (FF), internal model control (IMC) and the proposed $H_\infty$ control, are tested. Comparative simulation results are provided in Fig.8 and Fig.9. It is shown that the IMC can achieve best steady-state performance (i.e. smallest regulation error) and transient performance (i.e. fastest convergence speed). It is reasonable since the plant model and its inverse model are all directly utilized in the control implementation. Among other approaches, the $H_\infty$ control gives smaller transient overshoot as well as the steady-state regulation error. The PI control has similar transient to FF control but gives larger steady-state error.
- **Turbine trip**: To evaluate the compensation for the windup effect, simulations are also performed with a turbine trip between 550-650Sec as [8]. Comparative regulation results are depicted in Fig.10, for which the IMC controller allows disturbances rejection with a faster recovery speed. However, the IMC imposes aggressive control behavior, i.e. with valve stem position fluctuations, which is shown in Fig.11. On the other hand, the proposed $H_\infty$ control with AW gives smaller overshoot and steady-state regulation error and smoother transient performance compared to FF and PI. For more details, the corresponding controller outputs are also given in Fig.12, which shows that the proposed $H_\infty$ control with the AW compensation almost avoids the saturation issue, i.e. the control output is within [0,100].

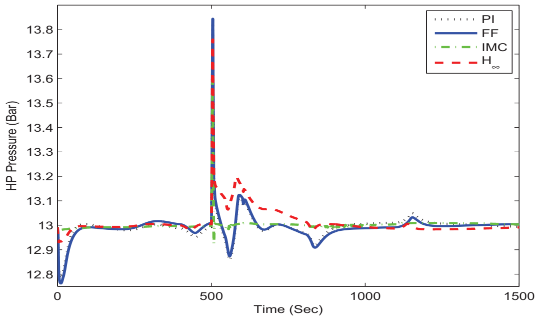

Fig. 10. HP regulation performance with a turbine trip.

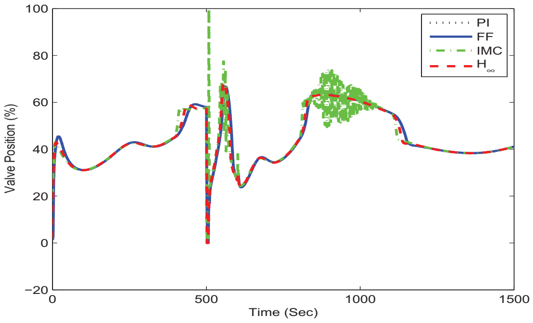

Fig. 11. Sliding valve position with a turbine trip.

### B. Discussion

From above simulations, it can be seen that the PI, FF, IMC and the proposed $H_\infty$ control with AW have their own characteristics:

**PI control**: It has a simple control structure for implementation, and no plant model is used. Although the disturbance rejection can be improved with high gains, the oscillated transient is obtained or even the stability may be lost in the worst case. Moreover, the integral windup will degrade the control performance in the presence of control constraints.

**FF control**: The disturbance model and the plant model inverse are superimposed in the feedback control as an extra compensation for the disturbance. Consequently, the improved steady-state regulation can be expected. The problem is that the disturbances are assumed to be precisely measurable, and the plant models are assumed to be exactly known. Moreover, the robustness to modeling uncertainties

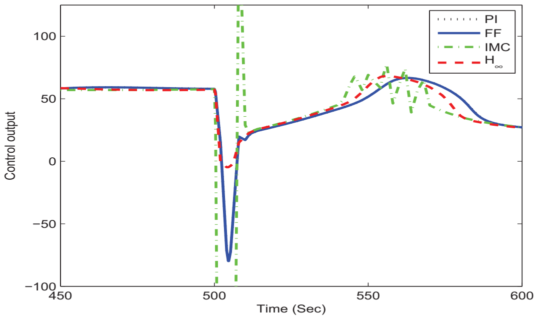

Fig. 12. Control output with a turbine trip.

are not considered.

**IMC control**: The plant model and its inverse are employed. Note in this paper the inverse model with a low pass filter is used as the feedback control, such that the disturbance rejection is guaranteed without any information on the disturbance measurement and its model. The robustness can be theoretically studied. Best output regulation performance has been achieved among the tested controllers. The complexity of the control design and implementation is moderate. However, the utilization of the model inverse as the feedback control action may introduce high gain and thus cause unexpected fluctuations and oscillation in the control actions (see Fig.11). This may be further remedied by redesigning the feedback control.

$H_\infty$ **control with AW**: The modeling uncertainties can be explicitly considered in the $H_\infty$ control synthesis, and 2-DOF feedback control also allows for the disturbance rejection with guaranteed robustness and performance. The valve control saturation is specifically compensated, which can further improve the transient performance when saturation occurs. However, a control with relatively high order may be derived following this synthesis, and the subsequent order reduction is necessary in the practical applications.

## VI. Conclusions

System identification and advanced robust control is studied for a helium liquifier to regulate the discharge pressure of compressor station. Time-varying heat loads are applied in the reservoir to simulate dynamic responses. An anti-windup framework is adopted to compensate for the control valve saturation.

Comparative simulations conducted in the software EcosimPro reveal that the proposed robust AW control scheme works well in the presence of control valve saturation. It gives designers more freedom to tradeoff the robustness and performance (i.e. the modeling uncertainties and disturbance rejection are explicitly considered in the control synthesis). However, the control order reduction needs to be studied before applying this control scheme to actual system. On the other hand, among the tested controllers (PI, FF, IMC and $H_\infty$), IMC can achieve good regulation and disturbance rejection performance in terms of transient and steady-state. Nevertheless, the possible high gain control due to the model inverse may trigger the valve saturation and thus result in aggressive control actions, which may be overcome by redesigning the feedback control part. Moreover, the frequency-domain identification approach provides fairly precise models that cover system dynamics among a wide frequency band.

# Trajectory Tracking of Exothermic Batch Reactor using NIR Spectroscopy

**Olufemi Osunnuyi* Ognjen Marjanovic* Jian Wan* Barry Lennox***

* *School of Electrical and Electronic Engineering, The University of Manchester*

**Abstract:** The control of exothermic chemical batch reactors has received much attention in literature over the years for their increasing importance in manufacturing industries and also the unique quality control challenges that they provide. However, most of the control schemes proposed to deal with these challenges make use of models that implicitly control the product quality. For example it is assumed that a control scheme that successfully regulates the reactor temperature along an *apriori* calculated optimal profile should imply satisfactory quality trajectory control. In this paper it is shown that this assumption is not robust enough to deal with some kinds of disturbances that may occur during the batch. It is also shown that product quality control can be greatly improved by proposing a new control scheme that makes use of NIR spectroscopic measurements as feedback information for a quality control system. The results of two controllers using this scheme are compared with a more widely used implicit control strategy in two test cases with unmeasurable system disturbances.

***Keywords: Batch process, Near Infrared Spectroscopy***

## I. INTRODUCTION

Batch and semi-batch processes are gaining increasing importance in manufacturing industries. Due to the flexibility they offer they are prevalent in the polymer, pharmaceutical and specialty chemicals industries where the focus is on the production of low-volume, high-value added products. An example of a batch process is the chemical batch reactor where the batch operation consists of charging the reactor, controlling the reactor temperature to meet some processing criterion, shutting down and then emptying the reactor. There is a steady increase of heat required during the initial phase of the batch to obtain the desired reaction temperature after which appropriate cooling is required to maintain the required temperature for the remainder of the batch [1, 2]. Previously not much attention was paid into how the reactor temperature reached the desired set points. However, due to work done on obtaining optimal reactor profiles so as to increase the yield of the desired product, research work subsequently focused on trajectory tracking control of batch reactors [3-5].

However, challenges occur when trying to implement reliable trajectory tracking control systems in batch processes due to the absence of steady state operation which requires the controller to track a highly transient profile within a short operating regime [6]. Some other unavoidable inherent characteristics include presence of time-varying and nonlinear dynamics, multitude of unmeasured disturbances such as concentrations of various raw materials, and the presence of irreversible behaviour which all inevitably affect the reliability of overall quality control [7]. There has been quite a bit of literature dedicated to improving the quality of control in this regard. For instance, the capability to track the optimal reference profile of the reactor temperature for various kinds of dual-mode controllers was compared in [1]. Also, a multivariate control strategy based on empirical dynamic PCA models for the trajectory tracking of the optimal profile was developed in [8].

All these publications however, have been based on the assumption that the successful regulation of the reactor temperature should result in good control of the quality of the desired product. However, even if the adequate temperature control system is in place and the reactor temperature does follow closely its reference profile, there is no guarantee that the final product will meet its specifications [9]. For example if a disturbance occurred that altered the dynamic relationship between the product quality and the reactor temperature, the production of the product quality will depreciate despite successful regulation of the reference temperature profile. Hence, the control objective should be focused on controlling variables that are more directly related to the product quality.

In a quite a number of process industries, Near-infrared (NIR) spectroscopic measurements are widely used in providing a more direct quantification for the quality of the product. NIR spectroscopy is based on the absorption of electromagnetic radiation at wavelengths in the range 780–2500 nm [10]. This frequency range covers mainly overtones and combinations of the lower-energy fundamental molecular vibrations making the NIR intensities significantly weaker than the fundamental bands from which they originate [11]. Thus, the low molar absorptivity of NIR bands permits operation in the reflectance mode and hence the non-destructive recording of spectra of solid samples with minimal or no pre-treatment, thereby substantially increasing the throughput [12, 13]. Uses of NIR spectroscopy are widespread in the pharmaceutical industry to test raw materials, control product quality and monitor processes [12-15]. NIR analytical techniques have also found popularity in the food industry being routinely used for the compositional, functional and sensory analysis of food ingredients, process intermediates and final products [10].

978-1-4673-1560-9/12/$31.00 ©2012 IEEE

Hence, the integrity of the quality of information provided by the NIR spectra can be exploited as essential feedback information used by the control system to enable enhanced quality production.

In this paper a quality control scheme that uses NIR spectroscopic measurements for the control of an exothermic batch reactor is proposed. In addressing the evident problem of dealing with the enormous amount of NIR spectra data two different controllers were designed and both compared with a conventional implicit reactor temperature controller using two different case studies.

## II. METHODLOGY

### A. Introducing NIR Measuring Point

The most widely used method of controlling exothermic batch reactors involves regulating the reactor temperature along an optimal profile which has been calculated offline. The intention being that this optimal profile will help yield the product quality trajectory that maximises the conversion of the desired product. One of the most common forms of this implicit control scheme is the Temperature Cascaded Control (TCC) shown in *Fig 1*. TCC uses cascade control for the control of the reactor temperature. The slave controller controls the jacket temperature, whose setpoint is determined by the reactor temperature controller.

It can be observed in *Fig 1* that the control loop is closed with the reactor temperature and hence will only reject disturbances that occur within the loop ($m_{d1}$) i.e. on $G_1$. An example of this disturbance could be a change in the heat transfer coefficient. However, when dealing with disturbances occurring outside this loop ($m_{d2}$), i.e. on $G_2$, the regulation of the reactor temperature proves incapable of tracking the desired trajectory for product quality. The reason being that the disturbance $m_{d2}$ changes the underlying relationship between $T_R$ and $M_{ABCD}$; hence the reactor temperature trajectory ought to change to yield the desired conversion of *Mc*. The best way of solving this problem is to introduce a new measuring point in the reactor that measures a variable that is directly related to the product quality, thus enabling the incorporation of another control loop using this new variable as feedback as shown in *Fig 2*.
This relationship ensures that the setpoint to the reactor temperature is dynamic, as opposed to the TCC scheme. In this paper the NIR spectroscopic measurements are used as this feedback information.

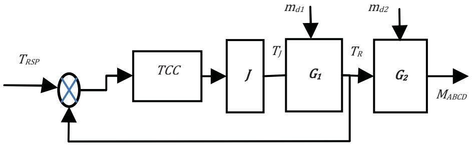

*Figure 1: Block diagram of Temperature Cascaded Control on Batch Process*

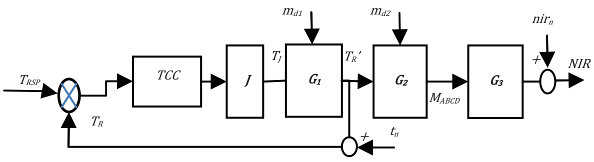

*Figure 2: Block Diagram of Batch Process producing NIR Spectra*

### B. Creation of Artificial NIR Spectra

The measured NIR Spectra is constructed under the assumption of Beer-Lambert Law for low concentration absorption media. This law enables us to obtain the NIR Spectra as the weighted sum of the individual linear mappings of the concentrations through their respective 'pure NIR spectra' [16]. These individual linear spectral mappings represent the NIR spectra of each component. And their sum is the NIR spectra of the entire batch run.
Assuming a matrix $M \in \mathbb{R}^{N\times m}$ which contains $m$ different compounds for $N$ number of samples in a batch run and $\theta \in \mathbb{R}^{A\times m}$ as the pure spectra matrix for these compounds with $A$ number of wave channels, then a complete batch of NIR Spectra ($NIR \in \mathbb{R}^{N\times A}$) can be calculated according to:

$$NIR(i,:) = \frac{M(i,:)}{(\sum_j^m M(i,j))} * \theta^T \qquad (1)$$

In order to obtain the pure spectra, an artificial spectra generator was designed to create pure spectra not related to any particular compound but sufficiently shaped to resemble forms of common pure spectra used in industry.
It was observed with non-artificial pure spectra that quite often the 'spectral peaks' were very similar in shape to standard Gaussian distribution. This basic assumption was essential in developing the code that would produce reasonable pure NIR Spectra for the purposes of the case studies considered in this paper.
Therefore in order to use this code in constructing a particular pure spectrum the following would need to be specified: the desired *number of spectral channels* (or wave numbers), the *number of Gaussian distributions* and the *maximum* and *minimum widths* (i.e. the width range) of these 'bell-shaped' Gaussian distributions. With randomly selected wave channels acting as mean centred positions ($\mu$) and with standard deviations ($\sigma$) also randomly chosen from the Gaussian width range, each Gaussian was generated on single a spectrum using the Gaussian function:

$$f(x;\mu,\sigma^2) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}} \qquad (2)$$

where $x$ represents the individual wave numbers.
The normalised sum of all these spectra incorporates all the individual Gaussians and thus forms a single pure NIR Spectrum. This procedure is repeated for as many compounds are present in each specific simulation. An example of artificially generated pure spectra for four compounds is shown in *Fig 3*.

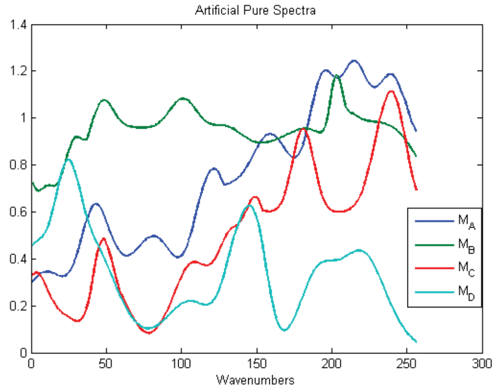

*Figure 3: Sample of Artificially generated pure NIR Spectra*

## C. Quality Control Methodology

### 1) NIR Data Reduction for SISO Control

The control scheme used to regulate the product quality is achieved by closing the loop at the new NIR spectra measuring point as shown in *Fig 4*.

When closing the new control loop a new block $Y$ is included because of the large amount of feedback information that is typical of NIR measurements. In this scheme block $Y$ is used to reduce the number of variables that is fed back to the new quality controller $C_q$. In this paper, in which a SISO simulation is considered for the case study example, block $Y$ represents two different data reduction techniques.

The first method of data reduction is a *wavenumber-selector* in which the most appropriate wavenumber for control is used. The selection of the appropriate wavenumber is very important because a wrong selection will lead to very poor control. One way of selecting the most appropriate wavenumber to control is by selecting the peak amplitude occurring in an NIR sample. However, this approach is based on trial and error. In this paper, the wave number from the NIR reference spectra with the largest variance was used. The reason for this choice is that the highest varying wavenumber will contain the best qualitative information of $G_2$ and also the highest amplitude does not necessarily imply the highest varying wavenumber as shown in *Fig 5*.

The second data reduction technique used was making block $Y$ a Principal Component Analysis (PCA) model. This reduces each fed back NIR spectrum into a specified number of latent PCA variables based on the extraction of the largest possible variance in the data set.

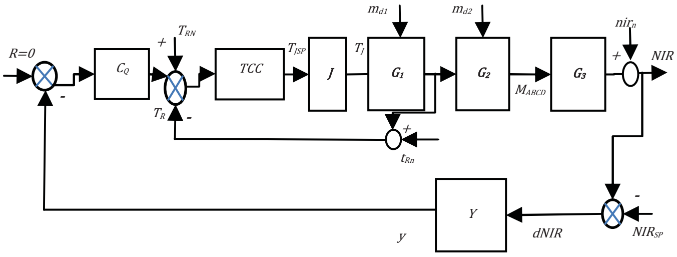

*Figure 4: Quality Controller implemented on Batch Process using NIR Spectral measurements*

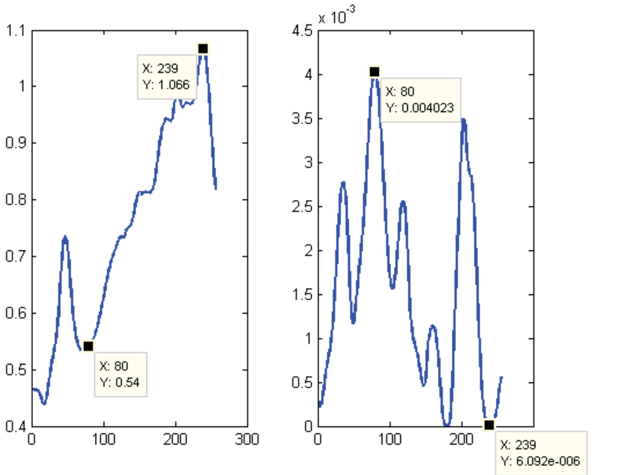

*Figure 5: Single NIR spectrum and variation spectrum of entire batch spectra*

In the case study of this paper, the results of controllers using these two choices of $Y$ were compared with that of TCC.

### 2) Deviation Control

Finally, rather than tracking the selected NIR reference wavenumber or the corresponding PCA score trajectory the control requirement in this quality control loop is to minimise the deviation from the quality variable trajectory. This takes into account the advantage of possessing the nominal reactor temperature trajectory which is subsequently added to the setpoint of the quality controller. Quite often the Achilles heel of trajectory tracking control is the wide operating range that the process variables cover during the batch.

By subtracting this dominant transient from the NIR spectrum before feedback the control requirement is in effect reduced to a less complex setpoint tracking and causes the speed of the controller's response to increase. In other words the batch control problem becomes similar to a continuous control problem.

# III. CASE STUDY

## A. Specification of Model

As a benchmark case to test the control scheme shown in *Fig 4* on, modifications were made to the nonlinear exothermic batch reactor model used by Cott and Macchietto [2] (schematically shown in *Fig 6*) to incorporate NIR Spectral measurements. This model has also been used by Aziz [1] and all of the model parameter values are the same as used in the latter paper except for the time constant of the jacket temperature $T_J$ ($\tau_J$) which is now 5mins as opposed to 3mins and the rate constant 1 for reaction 1 ($k_1^1$) was changed from 20.9057 to 20.8057. The sample time is 30s.

The control objective in the initial papers that have used this model is to control the reactor temperature by adjusting the setpoint to the inlet jacket temperature.

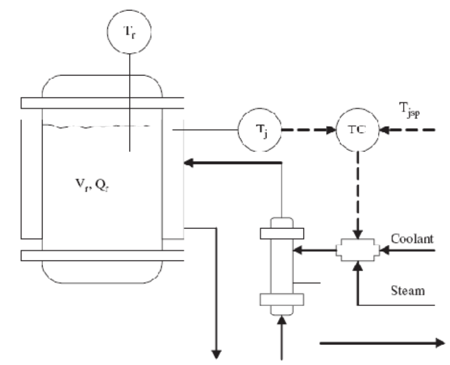

*Fig 6: Schematic of a chemical batch reactor* [17]

The reactions taking place are as follows:

$$A + B \xrightarrow{R_1} C \tag{3}$$

$$A + C \xrightarrow{R_2} D \tag{4}$$

Where *A* and *B* are the raw materials, *C* is the desired product, *D* is the waste product and $R_i$ is the reaction rate for reaction *i*. The dynamic equations of the process that form block $G_2$ are:

$$\frac{dM_A}{dt} = -R_1 - R_2 \tag{5}$$

$$\frac{dM_B}{dt} = -R_1 \tag{6}$$

$$\frac{dM_C}{dt} = +R_1 - R_2 \tag{7}$$

$$\frac{dM_D}{dt} = +R_2 \tag{8}$$

$$R_1 = k_1 M_A M_B \tag{9}$$

$$R_2 = k_1 M_A M_C \tag{10}$$

$$k_1 = e^{\left(k_1^1 - \frac{k_1^2}{(T_R + 273.15)}\right)} \tag{11}$$

$$k_2 = e^{\left(k_2^1 - \frac{k_2^2}{(T_R + 273.15)}\right)} \tag{12}$$

Where $M_i$ (*kmol*) is the number of moles for component *i*, $k_i^j$ is rate constant *j* for reaction *i* and block $G_3$ which converts raw materials and products into a combined NIR Spectra is as given in equation (1).

The reader is referred to the original publications for a more complete description of the model which include the description of block $G_1$.

## *B. Test Case Description*

The evaluation of the performance of the three controllers will be carried out on two different test cases. The controllers to be compared are:

a) *TCC* (PID)

b) *Wn-PID* (i.e. $C_q$ being a PID controlling a single wave number)

c) *Sc-PID* (i.e. $C_q$ being a PID controlling the first PCA score only).

The two simulated test cases are to evaluate the controllers' ability to reject disturbances occurring at $G_1$ ($m_{d1}$) and $G_2$ ($m_{d2}$) respectively:

TEST 1: A drop in the heat transfer coefficient, which occurs due to deterioration of the thermal jacket over a period of time and causes a change in the operating conditions. This will test the robustness of the controllers in reacting to a change in an unmeasured parameter.

TEST 2: A 2% increase in the rate constant 1 for reaction 1($k_1^1$). This causes a disturbance in the reaction rate of reaction 1 and therefore fundamentally changes the model relationship between the reactor temperature and the reactants (and hence products) for which the controllers were nominally designed for.

## *C. Controller Assessment*

Performance Index (PI): Under most industrial applications constructing a *PI* using the measurement of $M_C$ is not feasible due to the extremely high cost of purchasing quality analysers. However, because a simulation example is being used it was convenient assessing the performance of the controllers using $M_C$ and at the same time easily adapting this *PI* to the NIR spectra as well.

The MAE (mean absolute error) of the $M_C$ of each controller from the nominal trajectory was calculated as follows:

$$MAE_C = \Sigma_i^N \frac{|M_C(i) - \overline{M}_C(i)|}{N} \tag{13}$$

The same was calculated for all the wavenumbers of the NIR spectra. And to combine these metrics into a singular measure ($MAE_{NIR}$) the square root of the sum of the squared scaled mean absolute errors was used.

## *D. Results and discussion*

TEST 1: *Fig 7* and *Fig 8* show the responses of all three controllers to a change in the heat transfer coefficient. When the heat transfer coefficient decreases there is less flow of heat from the inlet jacket to the reactor which results in a rapid rise in the reactor temperature. The controllers are required to respond quickly to this change to avoid a large overshoot of the reactor temperature which would cause the off-specification production of the desired product. In both *Fig 7* and *Fig 8* it is observed that the quality controllers responded quicker to this change than the TCC. The extra control loop enables additional product quality-related feedback information to the jacket temperature and a quicker adjustment than that of the TCC.

Also, of the two quality controllers *Fig 7* and *Fig 8* show that the Sc-PID reacts more rapidly to the disturbance when compared to the Wn-PID. This is due to Sc-PID using information that more comprehensively represents the system dynamics of the reactor than the Wn-PID. This advantage is clearly represented in *Fig 7b* where the output of Sc-PID signals a further and quicker lowering of the jacket temperature than the Wn-PID. The effect of this as seen in *Fig 8a* is a lower jacket temperature drop particularly at the end of the heating phase of the reactor, resulting in a lower reactor temperature overshoot and better tracking of the optimal profile. Overall, the effect of tracking the desired product trajectory is shown in *Fig 8b* to be significantly better when using Sc-PID and the performance indices in *Table 1* show considerably lower values for the quality controllers –with Sc-PID being the lowest –than that of the implicit TCC.

TEST 2: *Fig 9* and *Fig 10* give the responses of all three controllers to a disturbance in the reaction rate due to an increase $k_1^1$ responsible for producing *C*. With this disturbance occurring at $G_2$ in *Fig 4*, the TCC lacks any essential feedback data informing it to adjust the reactor temperature to suit the new dynamic relationship. Therefore as shown in *Fig 9a* the TCC successfully tracks the now sub-optimal profile which results in very poor tracking of the desired product trajectory and a selected wavenumber (80) as show in *Fig 10a* and *10b*. Using an implicit product quality control scheme (such as TCC) essentially loses the batch in such conditions. Whereas the product quality-related information supplied by the NIR spectroscopic measurements enables the quality controllers to create a new optimal trajectory for the reactor temperature as seen in *Fig 9a*. By reducing the overall temperature of the reactor in the presence of the disturbance there is a closer tracking of the quality variables as seen in *Fig 10a* and *Fig 10b*.

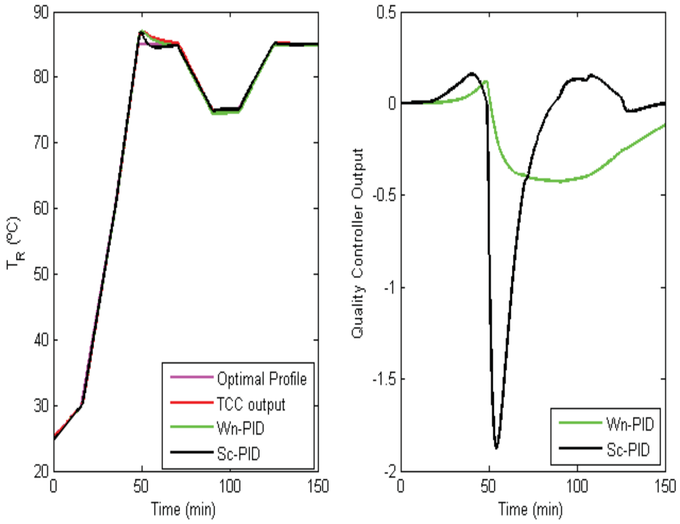

*Figure 7: a) Responses to change in heat transfer coefficient in Reactor Temperature and b) Quality controller outputs*

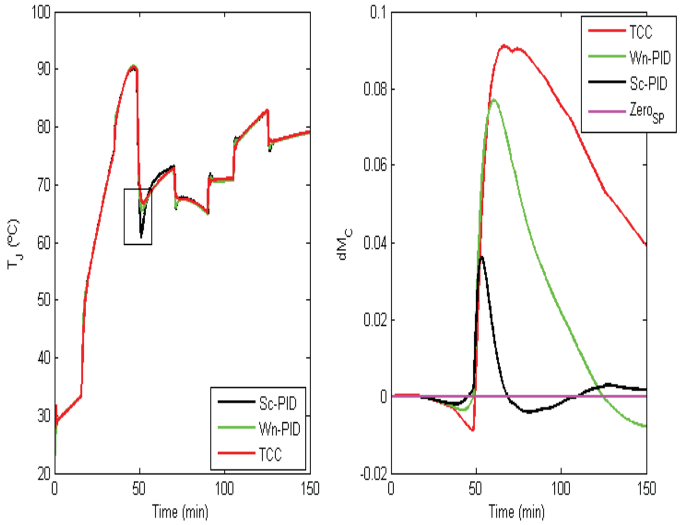

*Figure 8: a) Responses to change in heat transfer coefficient in Jacket Temperature and b) Deviation from nominal trajectory in $M_C$*

However, a much better performance of the Sc-PID in comparison to the Wn-PID is again noticed. There is a much quicker and settled response to the presence of this disturbance from the Sc-PID when observing the quality controller outputs of *Fig 9b*. The reason for this once again is that the first PCA score, which reflects the entire NIR Spectra, contains a lot more system information than any single wave number even when it is the highest varying wavenumber used.

These performances are again reflected in the *MAE* values of *Table 1*. The quality controllers far outperform the TCC, with the Sc-PID also proving to be better than the Wn-PID. It is worth noting that when the same test was carried out with Wn-PID to control the peak wavenumber (i.e. $Wn_{239}$) as opposed to the highest varying wavenumber (i.e. $Wn_{80}$), the performance index values returned were $MAE_C = 0.7216$ and $MAE_{NIR} = 0.4809$ for $Wn_{239}$. This very poor performance highlights the need to ensure the appropriate selection of a wavenumber.

## IV. CONCLUSION

This paper has investigated the use of NIR spectroscopic measurements as feedback for trajectory tracking of the product quality of exothermic batch reactors. This provides a more direct form of tracking the desired product quality as opposed to the implicit form of quality control quite often employed.

Instead of the control objective being the trajectory control of the reactor temperature, the objective was modified to minimising the deviation of a product quality related variable from its nominal trajectory. This scheme not only enables the controller to respond to various disturbances affecting different components of the reactor dynamics, but also greatly increases the speed of the controller's response as well.

These were shown by comparing the results of a standard Temperature cascade control (TCC) scheme with two controllers that utilise NIR spectra as feedback information. The first of these two controllers is Wn-PID, which minimises the deviation of the highest varying wavenumber of the nominal NIR batch from its setpoint trajectory, and the second being Sc-PID, which minimises the deviation of the first PCA score from its nominal trajectory. The results of the two tests carried out reveal that the quality controllers far outperform the TCC. However, the Sc-PID consistently outperformed Wn-PID owing to the fact that the first PCA score contains significantly more information than any single wave number.

| Disturbance Type | Controller | $MAE_C$ | $MAE_{NIR}$ |
|---|---|---|---|
| HTCC | TCC | *0.0459* | *0.0256* |
| | Wn-PID | *0.0197* | *0.0097* |
| | Sc-PID | *0.0038* | *0.0020* |
| RR-disturbance | TCC | *0.7103* | *0.4009* |
| | Wn-PID | *0.2802* | *0.1258* |
| | Sc-PID | *0.0778* | *0.0318* |

*Abstract* —**The dynamics of large scale circulating fluidized bed (CFB) boiler power plant shows the behaves of large time delay, complex coupling and nonlinearities, which brings difficulties for controller design to improve the plant performance. This paper firstly introduces a well-established and validated nonlinear model of a 300MWe CFB power plant, and then the model is simplified through analysis and approximation which could show clearly the reason of difficulties associated with controller design. It is found that the coupling and nonlinearity mainly come from the opening of main steam governing valve under various load conditions, and it is hard to completely decouple the multivariable system. To avoid the difficulties of decoupling, a decentralized PID control system is finally proposed to control the unit power and main steam pressure after nonlinear model transformation. The simulation results show that the control system has improved dynamic performance in load reference tracking for a wide range of load changes, and also good disturbance rejection to the coal quality variation. The analysis and control in this paper provide the first step to move forward for future control quality improvement and advanced control strategy study.**

***Keywords- CFB control; nonlinearity; decentralized control; PID controller***

## I. INTRODUCTION

As one of the promising clean coal utilization technologies, the circulating fluidized bed (CFB) boiler has gained rapid development in recent years [1]. Compared with traditional pulverized coal-fired (PC) power plant, CFB power plant offers the distinct advantages such as more fuel flexibility, lower pollution emission, wider operation range and higher combustion efficiency. Meanwhile, the wider operation range and complicated combustion process brings more nonlinearities into the unit dynamics. Since the heat release of coal combustion goes through repetitious circulating, the time delay and inertia from fuel disturbance of CFB boiler to the unit load fluctuation is much longer than those of PC power plants. And similar to the PC power plant, both of the fuel feed flow rate and governor valve position of steam turbine have prominent influences on the main steam pressure and unit power output simultaneously. Thus, the control of a CFB boiler power plant is a more challenging task than that of PC power plant, especially for its coordinated control system.

There are many advanced control strategies reported on the coordinated control of thermal power plants, such as active disturbance rejection control [2-3], nonlinear control based on approximate or exact feedback linearization [4-5], gain scheduling control [6], intelligent algorithm-based optimization control [7], etc. Most advanced control strategy simulation shows satisfactory control performance, but in fact it is hard to be implemented in the real power plant due to its complicated control design procedure or inconvenient tuning method. In addition, their applications to CFB power plants are rarely reported.

PID control is the most widely used control strategy in real control engineering of thermal power plants, usually merged with some amelioration elements such as unit load feed-forward compensations and nonlinear elements if necessary. In recent years, direct energy balance (DEB) control is very popular in coordinated control of thermal power plants in China. By integrating gain scheduling principle to eliminate the static gain nonlinearity [8], it can balance the turbine energy demand and boiler heat supply, and consequently improve the control performance under load variations. But the parameter tuning of DEB is of great dependence on engineers' experience and it is time-consuming to obtain final energy balance [2].

Since there is currently no well-accepted coordinate control strategy for CFB power plants, it is important to test any new control strategy in simulation using a full-scale verified nonlinear dynamic CFB power plant model before it can be implemented in practice. Some nonlinear models have been developed for CFB power plant in the last twenty years, and they are valuable in understanding the complex mechanisms of CFB process. However, those models have given very limited contributions to control system design or control engineering practice. The main reason may be that the modeling motivation is not for control study so that its dynamics has not been validated in the full load operation range to reveal the characteristic of nonlinearity, coupling, large time delay and high order inertia quantitatively. In addition, large scale CFB power plant has just accomplished its demonstration several

This work is funded by Tsinghua-Shenhua Strategic Cooperation Basic Research Project.

years before, so its modeling and control problem is still under investigation.

In this paper, a well-established nonlinear model of 300MWe CFB power plant in [9] is introduced. The model was built up to facilitate the coordinated control field adjustment. After reasonable model structure selection and model parameters identification, the nonlinear model is validated by using various load operation data in a real 300MWe CFB power plant. Thus it can be used to explore the coordinated control design of large scale CFB power plants.

The organization of this paper is as follows. In section II, we give an introduction to the nonlinear model of CFB power plant. In section III, the nonlinearity of CFB model is analyzed, followed with model approximation and reconstruction. In Section IV, the decentralized nonlinear control system is designed, and simulation results are presented in Section V to show its control ability on load reference tracking and coal quality disturbance rejection. Finally, the conclusion is given in section VI.

## II. A Nonlinear model of 300 MWe CFB power unit

Based on a nonlinear boiler-turbine model structure proposed in [10], a nonlinear boiler-turbine unit model for a 300MWe CFB power plant is developed [9] in Simulink to facilitate field commissioning of coordinated control system. The model structure is shown in Fig.1, and Tab. 1 gives the symbol annotations.

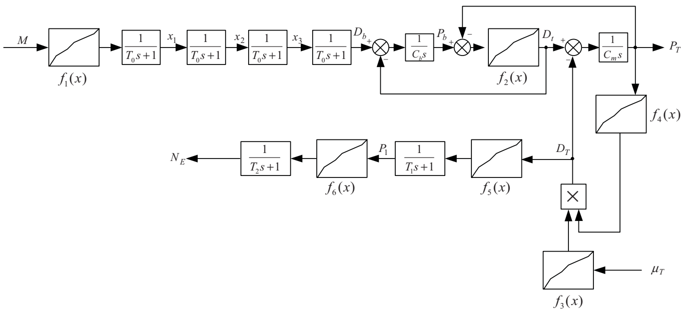

Figure 1. Nonlinear model structure of 300MWe CFB power plant

TABLE I. Symbol Annotation

| Symbol | Annotation |
|---|---|
| $M$ | Fuel flow rate |
| $\mu_T$ | Opening of steam turbine governing valve |
| $P_T$ | Main steam pressure |
| $N_E$ | Generator output power |
| $D_b$ | Heat produced in boiler |
| $P_b$ | Drum pressure |
| $D_t$ | Steam flow rate generated by boiler |
| $D_T$ | Inlet steam flow rate of turbine |
| $P_1$ | First stage pressure of turbine |
| $T_0,T_1,T_2$ | Time constants |
| $C_b$ | Heat storage coefficient |
| $C_m$ | Volume storage coefficient |
| $f_i(x)$,<br>$i=1,\cdots,6$ | Nonlinear mapping functions |
| $x_1,x_2,x_3$ | Intermediate state variables |

In Fig.1, nonlinear mapping function $f_i(x), i=1,\cdots,6$ is used to depict the static gain nonlinearity with load condition changes. They are identified by using the full-scope operating data of a real 300MWe CFB power plant [9]. The time constants $T_0,T_1,T_2$ and coefficients $C_b$ , $C_m$ are also identified from operating data of the same power plant in transient processes. Their values can be found in Appendix Tab. II and III.

Denote the system state $X$ and output variable $Y$ as:

$$\begin{aligned} X &= [x_1,x_2,x_3,D_b,P_b,P_T,P_1,N_E]^{\mathrm{T}} \\ &= [x_1,x_2,x_3,x_4,x_5,x_6,x_7,x_8]^{\mathrm{T}} \end{aligned} , \quad (1)$$

$$Y=[P_T,N_E]^{\mathrm{T}}=[y_1,y_2]^{\mathrm{T}} , \quad (2)$$

then the CFB model shown in Fig. 1 can be expressed as follows:

$$\begin{cases} \dot{x}_1 = \dfrac{1}{T_0}[-x_1+f_1(M)] \\ \dot{x}_2 = \dfrac{1}{T_0}(x_1-x_2) \\ \dot{x}_3 = \dfrac{1}{T_0}(x_2-x_3) \\ \dot{x}_4 = \dfrac{1}{T_0}(x_3-x_4) \\ \dot{x}_5 = \dfrac{1}{C_b}[x_4-f_2(x_5-x_6)] \\ \dot{x}_6 = \dfrac{1}{C_m}[f_2(x_5-x_6)-f_4(x_6)\cdot f_3(\mu_T)] \\ \dot{x}_7 = \dfrac{1}{T_1}[f_5(f_4(x_6)\cdot f_3(\mu_T))-x_7] \\ \dot{x}_8 = \dfrac{1}{T_2}[f_6(x_7)-x_8] \end{cases} , \quad (3)$$

$$Y=[x_6,x_8]^{\mathrm{T}} \quad (4)$$

Obviously, it is a nonlinear model due to the involvement of six nonlinear gain functions $f_i(x), i=1,\cdots,6$ .

To ensure that the power units can response quickly to grid load demand while maintaining the key parameters within their permitted limits, the coordinated system of a CFB boiler power plant should manipulate the control variable $M$ and $\mu_T$ to meet the following specifications:

(1) For a variable load reference, the unit load should follow load reference closely, and the main steam pressure fluctuation should be as small as possible.

(2) For a fixed load reference, the internal disturbance from combustion system should have little influence on the main steam pressure and unit load.

## III. MODEL APPROXIMATION

By plotting all the nonlinear mapping functions $f_i(x), i = 1,\cdots,6$, it is noticed that the nonlinearities associated with $f_i(x), i = 1,2,5,6$ are very close to linear relationship, so they can be linearized as:

$$f_i(x) \approx k_i x, i = 1,2,5,6\,, \tag{5}$$

where $k_i, i = 1,2,5,6$ are constant coefficients. In this way, the nonlinear model (3)(4) can be approximated as:

$$\dot{X} = \begin{bmatrix} -\frac{1}{T_0} & 0 & & \cdots & & & & 0 \\ \frac{1}{T_0} & -\frac{1}{T_0} & 0 & & & & & \\ 0 & \frac{1}{T_0} & -\frac{1}{T_0} & 0 & & & & \\ 0 & 0 & \frac{1}{T_0} & -\frac{1}{T_0} & 0 & & & \vdots \\ & & 0 & \frac{1}{C_b} & -\frac{k_2}{C_b} & \frac{k_2}{C_b} & & \\ \vdots & & & \ddots & \frac{k_2}{C_m} & -\frac{k_2}{C_m} & 0 & \\ & & & & 0 & 0 & -\frac{1}{T_1} & 0 \\ 0 & 0 & & \cdots & & 0 & \frac{k_6}{T_2} & -\frac{1}{T_2} \end{bmatrix} X + \begin{bmatrix} \frac{k_1 M}{T_0} \\ 0 \\ 0 \\ 0 \\ 0 \\ -\frac{f_4(x_6) f_3(\mu_T)}{C_m} \\ \frac{k_5}{T_1} f_4(x_6) f_3(\mu_T) \\ 0 \end{bmatrix} \tag{6}$$

$$Y = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix} X\,. \tag{7}$$

The simplified model is still a nonlinear model, and now the nonlinearity mainly comes from $f_4(P_T) f_3(\mu_T)$, especially the opening of governor valve $\mu_T$ for the fixed pressure operation.

We select a new control input $D_T$ instead of $\mu_T$ as:

$$D_T = f_4(x_3) f_3(\mu_T)\,, \tag{8}$$

and substitute (8) into (6), then we have

$$\dot{X} = \begin{bmatrix} -\frac{1}{T_0} & 0 & & \cdots & & & & 0 \\ \frac{1}{T_0} & -\frac{1}{T_0} & 0 & & & & & \\ 0 & \frac{1}{T_0} & -\frac{1}{T_0} & 0 & & & & \\ 0 & 0 & \frac{1}{T_0} & -\frac{1}{T_0} & 0 & & & \vdots \\ & & 0 & \frac{1}{C_b} & -\frac{k_2}{C_b} & \frac{k_2}{C_b} & & \\ \vdots & & & \ddots & \frac{k_2}{C_m} & -\frac{k_2}{C_m} & 0 & \\ & & & & 0 & 0 & -\frac{1}{T_1} & 0 \\ 0 & 0 & & \cdots & & 0 & \frac{k_6}{T_2} & -\frac{1}{T_2} \end{bmatrix} X + \begin{bmatrix} \frac{k_1 M}{T_0} \\ 0 \\ 0 \\ 0 \\ 0 \\ -\frac{D_T}{C_m} \\ \frac{k_5}{T_1} D_T \\ 0 \end{bmatrix}. \tag{9}$$

Thus the nonlinear model (6)(7) can be rewritten in a linear state space representation as follows:

$$\begin{cases} X = AX + BU \\ Y = CX \end{cases}, \tag{10}$$

where,

$$A = \begin{bmatrix} -\frac{1}{T_0} & 0 & 0 & & \cdots & & 0 & 0 \\ \frac{1}{T_0} & -\frac{1}{T_0} & 0 & & & & & 0 \\ 0 & \frac{1}{T_0} & -\frac{1}{T_0} & 0 & & & & \\ 0 & 0 & \frac{1}{T_0} & -\frac{1}{T_0} & 0 & & & \vdots \\ & & 0 & \frac{1}{C_b} & -\frac{k_2}{C_b} & \frac{k_2}{C_b} & & \\ \vdots & & & \ddots & \frac{k_2}{C_m} & -\frac{k_2}{C_m} & 0 & 0 \\ & & & & 0 & 0 & -\frac{1}{T_1} & 0 \\ 0 & 0 & & \cdots & & 0 & \frac{k_6}{T_2} & -\frac{1}{T_2} \end{bmatrix} \tag{11}$$

$$B = \begin{bmatrix} \frac{k_1}{T_0} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -\frac{1}{C_m} & \frac{k_5}{T_1} & 0 \end{bmatrix}^{\mathrm{T}} \tag{12}$$

$$C = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix} \tag{13}$$

$$U = [M \quad D_T]^{\mathrm{T}} \tag{14}$$

## IV. CONTROL SYSTEM DESIGN

Both of the controllability matrix and observability matrix of system (10-14) have full rank, so the system is completely controllable and observable, a full-state feedback controller can be designed to move the initial states to any specified condition in a finite time interval without considering input constraints. Considering the motivation of control system implementation in the real CFB power plants, only PID controllers are adopted in this paper instead.

For linear system (10-14), a two-input-two-output transfer matrix can be derived as follows:

$$\begin{bmatrix} P_T(s) \\ N_E(s) \end{bmatrix} = \begin{bmatrix} g_{11}(s) & g_{12}(s) \\ g_{21}(s) & g_{22}(s) \end{bmatrix} \begin{bmatrix} M(s) \\ D_T(s) \end{bmatrix} \tag{15}$$

where,

$$\begin{aligned} g_{11}(s) &= \frac{k_1 k_2}{s(1+T_0 s)^4 (C_m C_b s + k_2 C_m + k_2 C_b)} \\ g_{12}(s) &= \frac{-(C_b s + k_2)}{s(C_m C_b s + k_2 C_m + k_2 C_b)} \\ g_{21}(s) &= 0 \\ g_{22}(s) &= \frac{k_5 k_6}{(1+T_1 s)(1+T_2 s)} \end{aligned} \tag{16}$$

It has a half-decoupled structure, so a local controller can be tuned separately for the second loop $g_{22}(s)$. Here a PID controller is employed for the sake of simplification:

$$c_2(s) = \frac{k_{p2}}{k_5 k_6} \frac{(1+T_1 s)(1+T_2 s)}{s(1+T_2 s / T_f)}, \tag{17}$$

so that the open-loop transfer function of second loop approximates as

$$g_{2o}(s) = g_{22}(s) c_2(s) \approx \frac{k_{p2}}{s} \tag{18}$$

For the first loop, it is hard to compensate completely the disturbance from $D_T$ to $P_T$ owning to the realization difficulty of decoupling transfer function as well as input constraints. An approximately decoupling controller, such as P or PD controller can be designed to obtain partly decoupling if necessary. Here, a PI controller is designed for the first loop to explore the ability of decentralized control structure:

$$c_1(s) = k_{p1} + \frac{k_{i1}}{s}, \tag{19}$$

The above two controller parameters are tuned as:

$$k_{p1} = 50,\ k_{i1} = 0.1,\ k_{p2} = 1,\ T_f = 10. \tag{20}$$

The closed-loop control structure of CFB coordinated control system is shown in Fig. 2. Since the first loop output $P_T$ is used to derive the second loop control action $\mu_T$, so it is actually a partial decoupled control system even if it is represented in a simple decentralized structure.

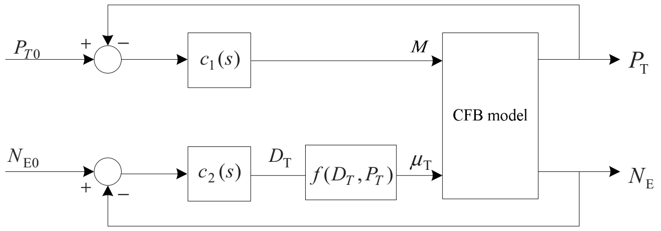

Figure 2. Control structure of CFB unit control

From the nonlinear mapping functions in Appendix, it is clear that nonlinear function $f_3(x), f_4(x)$ are both monotone increasing functions with constraints, their inverse functions exist in region of interest. Then it is realizable to derive the real control action $\mu_T$ from $D_T$ and $P_T$ as follows:

$$\mu_T = f(D_T, P_T) = f_3^{-1}[D_T / f_4(P_T)] \tag{21}$$

## V. Simulation Results

### A. Change load reference

Starting close-loop simulation from 210 MWe (70% load), at 1000 s the load reference increases to 250 MWe with a rate of 0.3 MWe/s, and at 5000 s the load reference decreases to 170 MWe with a rate of 0.3 MWe/s. The dynamic responses of power output and main steam pressure are shown in Fig. 3(a)-(b). It can be found that the load output can rapidly follow its reference closely, while keeps the disturbance on main steam pressure within a small range of ±1 MPa. The dynamics of fuel flow rate and valve opening are also given in Fig. 3(c)-(d), they behave relatively smooth.

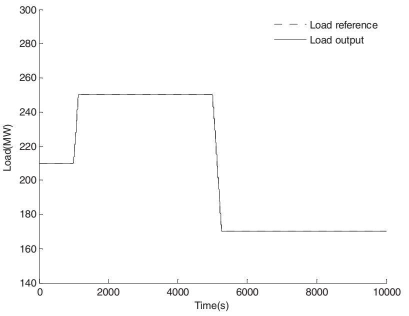

Figure 3(a) Load output response

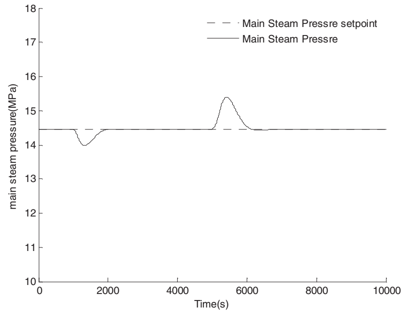

Figure 3(b) Main steam pressure response

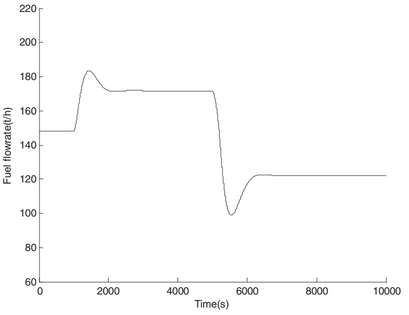

Figure 3(c) Fuel Flow rate response

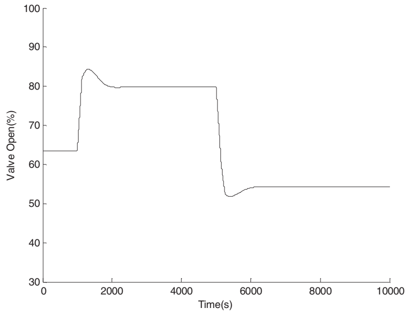

Figure 3(d) Valve Opening response

A simulation of larger load reference change is conducted, which is not shown in this paper for length limits. The simulation results indicates that the coordinated control system shows similarly good load following capacity without retuning the controller parameters for the situation that the manipulation of fuel flow rate and valve opening do not reach their limits.

### *B. Dynamics at fuel flow rate disturbances*

The coal quality variation will influence the operation of power plant greatly by bringing uncertainty to control system. Here, the coal quality variation is treated as a fuel flow rate disturbance. Firstly a step fuel flow rate disturbance of -50 t/h at 1000 s is conducted, then followed with a step fuel flow rate disturbance of 100 t/h at 5000 s, Figure 4(a)-(d) illustrate the dynamic responses of unit load, main steam pressure, fuel flow rate and valve opening.

It is obviously that the coal quality disturbance has no influence on load output owning to the rapid opposite direction manipulation of valve opening. Since the disturbance is added directly to the fuel flow rate, the main steam pressure shows obvious departure from setpoint value and has a positive correlation with the amplitude of fuel flow rate disturbance.

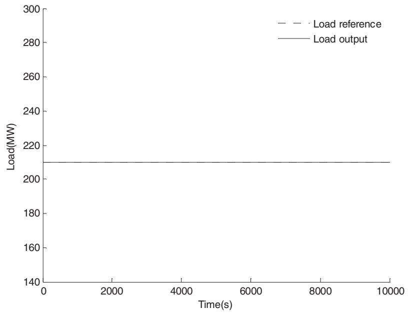

Figure 4(a) Load response at fuel flow disturbance

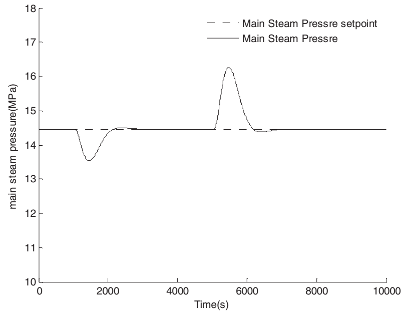

Figure 4(b) Main steam pressure response at fuel flow disturbance

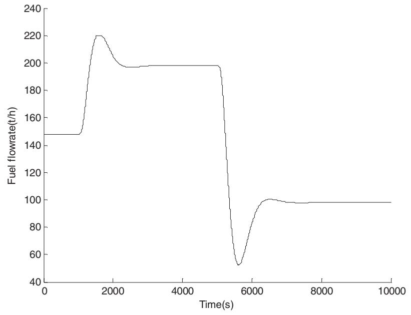

Figure 4(c) Fuel Flow disturbance

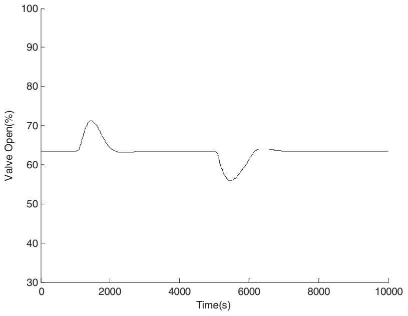

Figure 4(d) Valve Opening at fuel flow disturbance

## VI. CONCLUSION

In this paper, a well-established and validated nonlinear model of a 300MWe CFB power plant is introduced and analyzed to reveal its control difficulty. It is found that the nonlinearity firstly comes from static gain changing with load, then from the opening of steam turbine governing valve. After some model approximation, it is still hard to fully decouple the two-input-two-output system. Then a decentralized PID control is designed to control the unit load and the main steam pressure by defining a new control variable and transforming the nonlinear model into a linear formula. Simulation results show that the control system has good performance in load reference tracking for a wide load change in operation conditions, and also good disturbance rejection for the coal quality variation. The analysis and control in this paper is the first step to move forward for future control quality improvement and advanced control strategy study.

# Developing virtual laboratories for introductory control

J.A. Rossiter and Y. B. Shokouhi
Automatic Control and Systems Eng., University of Sheffield, UK.
e-mail: j.a.rossiter@sheffield.ac.uk

*Abstract*—**This paper focuses on student access to learning opportunities and in particular those where students can learn by trial and error, such as in laboratories. It is recognised that regular student access to real equipment is a challenge for many institutions and thus alternatives are required, such as remote access laboratories. However, even remote laboratories are non-trivial to make available and thus this paper focuses on virtual laboratories. It demonstrates how these can be formulated very efficiently, can be highly accessible and critically, enhance the student learning experience. Several examples of virtual laboratories are discussed.**

**Keywords:** Web accessible laboratories, independent learning, authentic learning

## I. Introduction

There has been a sizeable body of work in recent years focussed on the laboratory experiences of students within engineering and a reassertion of the long standing view that laboratories form a key component of the student learning experience Abdulwahed (2010). This view is also strongly made by accreditation bodes Council (2011). Nevertheless, it is recognised that laboratories are expensive (Hofstein and Lunuetta, 2004) and indeed not necessarily efficient learning activities. Consequently Universities must seek a balance between the benefits of students interacting with equipment and the corresponding expense and inefficiency Lindsay and Good (2005); Ma and Nickerson (2006).

### *A. Remote or web accessible laboratories*

Many Universities have bought large scale into the concept of remote laboratories, e.g. (RELOAD, 2010; Qiao et al., 2010; LILA, 2010; Nagy and Agachi, 2004; Trevelyan, 2004). These enable departments to overcome many of the constraints associated to putting students into a laboratory room: typically there are restrictions on the number of duplicate equipment sets which means running the same activity numerous times in order to allow the entire cohort to participate and thus puts corresponding pressures on timetables. Consequently, most undergraduate students may only gain access to equipment about once a fortnight, with the exception perhaps of their final year research project.

Remote laboratories overcome barriers such as the timetable as the laboratory is then available 24/7. In principle, these laboratories can also be much cheaper as duplicate sets are not required and moreover, there is a not a requirement to find space for students to access the equipment (many universities now deploy space charges). With the right interface, especially with a suitable webcam, it is clear to students using a remote laboratory that it is real equipment and the data they are receiving is authentic.

Nevertheless, remote laboratories also have significant failings. Where the activity has a relatively slow timescale, there is still a need to allocate students specific access times. Even when the activity has a fast timescale, students may still need access for 5-10 min to complete their tests and this would be a severe irritation to students in a queue for access. With large class sizes, it is apparent that remote and web accessible need not imply there is good accessibility, which in turn could lead to student frustration.

### *B. Virtual Laboratories*

One alternative to remote laboratories is a virtual laboratory (Foss et al., 2006; Guzman et al., 2006; Khan and Vlacic, 2006), that is one which emulates real equipment and has the appearance of being authentic, despite being in fact just a simulation. Of course these have limitations (Engum et al., 2003; Magin and Kanapathipillai, 2000) because they are not the real thing, but nevertheless they can be highly authentic if done well (Goodwin, 2010). Moreover, they can form an invaluable component of an overall student activity set Abdulwahed (2010); Callaghan et al. (2008) because they provide activities which emulate much more closely than paper exercises the actual equipment. More specifically, virtual laboratories can form an invaluable preparation for access to real equipment as they can encourage students to think through the key concepts and tests that are required, and thus enable much more efficient use of equipment. Recent work in Southampton is also exploring how good quality video and animation could similarly improve student preparation and this has equally been denoted a virtual experiment (Memoli, 2011).

The main advantage of a virtual laboratory is that the access is much improved over remote laboratories; in principle all students can access simultaneously (unless there are license restrictions on the associated software). This means students have fewer obstacles to engagement and learning through trial and error in an pseudo-authentic scenario.

### *C. Summary*

This paper focuses on the role and development of virtual laboratories. The role is largely to support student learning and provide an accessible pseudo-authentic experience which helps students relate lecture content to real life scenarios, and

978-1-4673-1560-9/12/$31.00 ©2012 IEEE

thus improve insight and understanding. However a secondary and equally valid role can be to facilitate preparation for a real experiment. The virtual laboratory can emulate activities and concepts required for the actual laboratory (Abdulwahed, 2010; Memoli, 2011) and thus enable students to prepare effectively.

The second contribution is to discuss the actual laboratories developed and give some evaluation from students on their views about these laboratories. The focus is on activities which support the learning of fundamental control engineering concepts.

## II. Supporting student learning through authentic activities

The priority for the author's department was to develop activities to support large cross faculty modules in modules related to control. Given the large size of the cohorts, access to equipment is very difficult in practice and thus remote activities were essential to give students access to more authentic scenarios. The topics of most interest within this paper are:

1) In year 1 students learn about modelling and system behaviours with most focus on 1st and 2nd order differential equation step responses. Some experimental activities were wanted to reinforce the concepts covered in lectures.
2) Also in year 1, students are introduced the concepts of feedback and PI control. There was a desire for activities that allow students to experiment with the PI parameters in both an emulated environment and on real equipment.

The developments follow the TRILAB concept to some extent.

- Students are introduced to the theory in lectures
- Students access a remote laboratory to test same ideas on real equipment and also to understand the differences.
- Students have virtual laboratories to practise in a pseudo-authentic environment.

Chronologically, the first two bullet points were developed first and thus this section will discuss the theoretical back ground and the remote equipment. The next section will focus on the third bullet point, which in fact will ultimately become the 2nd activity to help students prepare and thus is a key pedagogical element in the overall learning experience.

### A. *Creating a remote laboratory*

This paragraph is a summary of key points and is discussed in more detail in (J.A.Rossiter et al., 2011). The development of a web accessible laboratory is surprisingly easy and will be summarised in the following steps.

1) Connect up the hardware to the computer with a compatible I/O card. The authors found National Instruments cards easy to link into LabVIEW thus saving time.
2) Develop and test your LabVIEW virtual instrument (vi) or programmes' for communicating and controlling the experiment. The Front Panel window of the LabVIEW will be displayed to the user and it can be designed in a user friendly manner.
3) Once the experiment is working under a local computer it is a one click operation to use the web publishing tool to generate a web link for the vi and publish this link in your website. Students can then control the equipment via a web interface as if sitting next to the equipment.
4) There are some minor requirements on plug-ins for the browser to display correctly, e.g. Vision Development Module Run Time Engine and LabVIEW 2009 Run Time Engine.

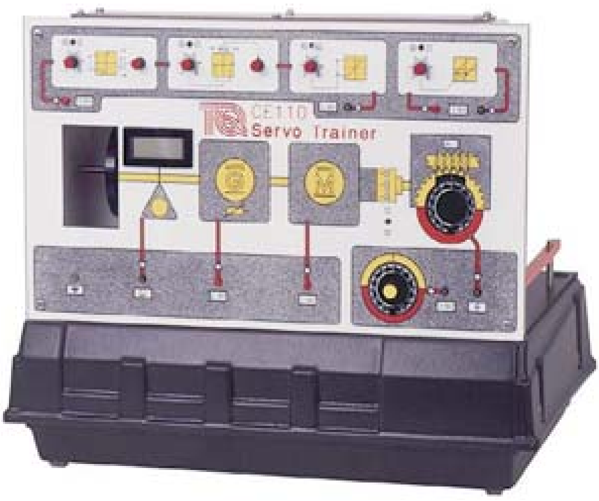

Figure 1. The DC servo equipment

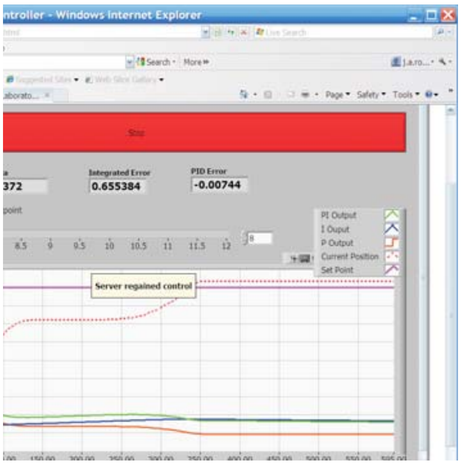
### B. *Activity 1 and equipment (J.A.Rossiter et al., 2011)*

The first activity is focussed on reinforcing student understanding of first order dynamics. In lectures students are taught to derive and analyse first order models and thus to understand the links between model parameters and behaviour as well as analogies between different systems. A laboratory can reinforce this by demonstrating:

1) Real systems do indeed have responses that are closely modelled by a first order response.
2) The system model parameters can be estimated reliably from measured data.
3) Real responses differ slightly from ideal behaviour.

The main parameters in a first order model are gain and time constant. Consequently the laboratory activity is split into three parts: (i) estimate the gain; (ii) estimate the time constant and (iii) compare the estimated model response with the actual behaviour.

The equipment selected is a simple DC Servo motor kit (see figure(1)) with analogue inputs and outputs. It consists of 5 different units in addition to nonlinearities. The students can see the axle rotation and the display showing angular velocity. Within the experiment the only input used is the input voltage as the response from voltage to angular velocity is approximately first order.



ntroller - Windows Internet Explorer

Integrated Error 0.655384

PID Error -0.00744

Figure 2. Interface for the stig equipment

The remote laboratory interface has three separate tabs. In tab one students modify the input voltage directly to estimate the steady state gain, positive dead-zone and negative dead-zone of the DC servo motor. Gain is given as the gradient of the input/output curve. In tab two, the time constant of the system is estimated using responses to a square wave input. In tab three, students enter their estimated gain and time constant and produce an exact step response to compare with the plots from tab two.

### C. Activity 2 and equipment

The second activity (internally denoted as 'the stig') is designed to reinforce student understanding of PI control and basic control concepts. The underlying objectives are for students to investigate:

1) The impact of changing gain with no integral.
2) The effect of changing integral with no proportional.
3) The potential of using proportional and integral together.

The equipment consists a cart on 2 metre long rails. The cart is moved by a motor. The underlying dynamics are such that in the future the same equipment will be suitable for experiments looking at 2nd order modelling and dynamics (e.g. under damped responses) as well as an introduction to feedback.

The remote interface is very simple in form. Students are able to choose a proportional term, an integral term and a set point. The system begins moving and the final interface is a button which allows them to stop the experiment at a point of their choosing. The graphical display (figure 2) shows the output position, the input signal, the output of the integral term and the output of the proportional term for the entire runtime.

The interesting point to note here is that there is clearly some stiction in the system so although, with patience, the system will progress close to the desired steady-state, it never quite gets there because the change in input needs to be large enough to get the system moving again and then it tends to jump. However, stiction aside, the expected behaviour does ensue so the experiment gives students a good insight into reality and the relevance of the theory covered in lectures. Moreover, it allows them to see the role of the integral term (blue line) and proportional term (orange line) in the overall input signal (green line); this is particular important for understanding the real system effects such as stiction because students can see the cart stalls even when the input (and integral term) is changing.

### D. Laboratory design: pedagogy and learning outcomes

Access to the equipment itself is not, in general, enough to support student learning. The authors have experienced significant frustrations due to software and hardware crashes which limit student access until the crash is noted and rectified manually. Although some crashes can lead to an automatic reboot J.A.Rossiter et al. (2011), this is not the case for all.

A second weakness of remote laboratories is that only one student can access these at a time. With small cohorts this may not be an issue, but with cohort sizes of 100 plus, the likelihood is that students will have similar free periods and will all try to access simultaneously. Consequently they may have to wait a substantial period to come first in the queue, and their position in the queue will not be obvious without substantial increase in complexity of coding at the server end. This weakness will limit their ability to learn by a large number of trial and error experiments, something staff may wish to encourage.

Consequently, the next section looks at how students can spend time focussing on learning concepts and thus require less time on the equipment to validate the authenticity of their learning.

## III. Virtual Laboratories to support preparation for remote laboratories

The key aim of the virtual laboratories is to provide maximum accessibility for students to practise. One could argue therefore that web interfaces such as (Khan and Vlacic, 2006; Guzman et al., 2006) are ideal. However, the downside of such laboratories is the skill and time required to develop them, as well as the need for a maintenance of an appropriate server. Consequently, the authors decided to follow a route which minimised the staff skill and time requirement, as this is pragmatic and increases the potential for more staff to participate.

In summary, it was decided to use MATLAB/SIMULINK as the base for virtual laboratories.

1) The relevant files can be distributed easily for students to use anytime and anywhere.
2) MATLAB is available on the University network and thus students have excellent access to the software. Many students also purchase a student version for home use or can get remote access to the University software with the relevant 'access code'.
3) The software is well understood by most staff and widely used, thus making resources easier to produce and share.

4) The author's department also has a well established server system which students can access remotely to run MATLAB files.
5) The GUIDE tool allows for relatively straightforward production of GUIs which make interaction easy and intuitive for students.

The virtual laboratories are designed as far as possible to emulate the physical laboratories so students go through the same steps and focus on the same concepts. This will allow them to become familiar with the key observations expected before accessing the equipment and moreover they are more likely to notice the key differences between the theory and the practice.

In terms of staff effort, each GUI took about half a day to create which is much quicker than requirements with alternative software choices.

### A. Virtual Modelling laboratory

This laboratory was focussed on 1st order modelling. To allow some non-linearity and add realism, the simulation is based on a simulink model which has simple first order dynamics but with some dead zones and measurement noise also added. The virtual laboratory was produced as single GUI (figure 3) which embodied all 3 activities of the experimental equivalent and hence it required:

- Three axes, one for each activity.
- Buttons for changing the input voltage and saving data.
- Boxes to enter the estimates for gain and time constant.

The top right axis shows the steady-state vs the input, marked by crosses, for different inputs and also a best estimate of the slope; clearly the slope is an estimate of gain. The input voltage is selected by a slider, a button requests a simulation with this value and another button confirms the data should be entered into the plot (so a student need not save all values). The little circle in the top middle emulates the spinning of the servo and rotates in real time on the GUI, as well as showing the steady-state speed. The reader will note some stiction is included in the simulation so there is no movement for small voltage inputs. For completeness, figure 4 shows the equivalent interface on the actual equipment. This has separate axis for positive and negative input voltages but otherwise is seen to have equivalent functionality: the webcam is used for students to read the speed, there is box to enter this reading and another button to *add data* to the axes - this data is also displayed in numeric form. Students are also encouraged to identify the dead zone and enter the observation into the relevant boxes.

The axis in the bottom left shows the responses to a square wave, with the same input amplitude as for the first figure. Some noise is added to encourage students to think about real issues. This display can be used to estimate the time constant.

The axis in the bottom right is used to simulate a model based on the gain and time constant estimates. Students must enter their estimates into the boxes provided.

The main objective of the GUI was to allow students to go through the same conceptual steps required for the remote laboratory. That is practise changing the input voltage, reading the steady-state output and then adding this data to the axis (hence the need to a deliberate button press). The remote laboratory will produce a similar figure containing the crosses, although in that case students need to estimate the slope themselves and then enter into a box. The bottom axis gives a very similar plot to that students would see on the real equipment, with a square wave response. From this, in both cases, the activity required is an estimate of time constant. Finally, the third activity in both cases is to use the gain and phase estimates to from an ideal 1st order model and simulate the step response. The intention is that students would therefore find engagement with the remote laboratory straightforward as well as being clear on the key learning outcomes, understanding first order responses.

### B. Virtual PI laboratory

This laboratory is based on position control of a cart (carrying a passenger) along a track. The requirement was for students to explore the impact of changing the PI parameters on performance. Hence the chosen GUI was chosen to be very simple in form as shown in Figure 5. There are simple sliders for entering the choice of proportional and integral terms. The top axis shows the target and output position curves (in figure 5 there is a steady-state offset as the integral is zero). The bottom axis is an animation and students see the passenger

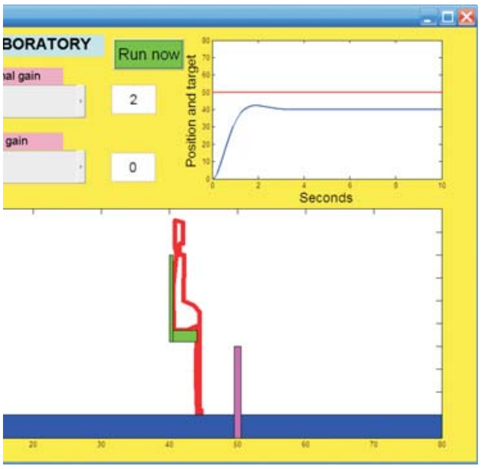

Figure 5. MATLAB GUI for PI control of position.

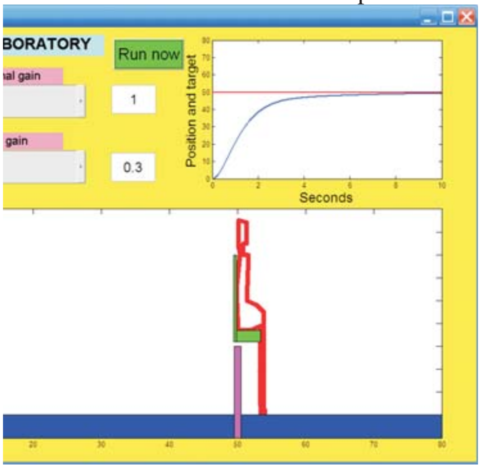

Figure 6. MATLAB GUI for PI control of position.

moving but ultimately stopping short of the target. Figure 6 shows a simulation with a non-zero integral where clearly the offset is removed.

For completeness, figure 2 shows the associated hardware laboratory interface, accessible via the web. Again, students need only set the PI parameters and while the same basic observations will follow, it is clear that the behaviour is far from ideal; this should give students something challenging to ponder.

## IV. Student evaluation

It is known that remote laboratories can be beneficial and hence the main focus of the evaluation here is on the efficacy of the virtual laboratories for enhancing the overall student learning experience. Students were asked a number of questions and the responses are summarised in Tables 1 and 2. Table 1 is a smaller student group who had the virtual laboratories paired with a hardware laboratory. Table 2 is a much larger group (over 200) who had the virtual laboratories solely for supporting learning, but not for assessment.

It is interesting to note that the second group were less positive overall, but this is probably a reflection of their engagement being formative rather than summative and hence many of this group will not have used the virtual laboratories effectively, if at all (many students only put in effort if 'it counts'). Indeed a question on an issue not related to this paper showed that only about 50% of the class had engaged with a key formative resource.

TABLE I
Student evaluation of virtual laboratories (ACS108).

| Question | Strongly agree or agree | Neither agree or disagree | Disagree |
|---|---|---|---|
| Virtual Laboratories (MATLAB GUIs) were easy to use and access | 89% | 7% | 4% |
| Virtual Laboratories helped me prepare for the remote laboratories | 75% | 21% | 4% |
| I felt more confident using the remote laboratories having first gone through the virtual laboratories | 50% | 38% | 12% |
| It was useful to see the differences between a simulation (ideal model of virtual lab) and the responses on real equipment. | 89% | 7% | 4% |
| The modelling virtual laboratory helped me understand the key parameters of gain and time constant | 75% | 18% | 7% |
| The STIG virtual laboratory helped me understand the role and impact of the key parameters of P and I | 82% | 14% | 4% |
| I think the department should produce more virtual laboratories to support preparation activities for laboratories. | 92% | 4% | 4% |
| I think the department should produce more virtual laboratories to support learning of key concepts. | 96% | 4% | 0% |

Where engagement was summative, that is for the ACS108 students, it is clear that the resources were useful for the majority. The relatively poor response on preparation for the actual remote laboratories is more likely a reflection of the poor reliability of the remote laboratories so that accessibility was poor and thus many students failed to do the hardware laboratory; this latter issue is an ongoing priority for technical staff.

## V. Conclusions

This paper has looked at the provision of laboratory activities within engineering curricula and proposed that the role of the virtual (and remote) laboratory has much more potential than is being exploited in most institutions. Virtual laboratories have the advantage of being accessible 24/7 and also allow parallel access by a large number of students, sometimes the whole cohort.

This paper has illustrated two simple uses of virtual laboratories. The most basic use is as a formative learning exercise, to allow students to practise with key concepts and thus to improve their understanding. A second and more integrated use links the virtual laboratories with real equipment and

TABLE II
STUDENT EVALUATION OF VIRTUAL LABORATORIES (ACS124).

| Question | Strongly agree or agree | Neither agree or disagree | Disagree |
|---|---|---|---|
| The virtual laboratories helped me understand the role of modelling and simulation in design. | 84% | 7% | 9% |
| Virtual Laboratories helped me prepare for the remote laboratories | 75% | 21% | 4% |
| The virtual laboratories helped me understand the role and impact of the feedback parameters P and I. | 49% | 35% | 16% |
| I think the department should produce more virtual laboratories to support the learning of key concepts. | 72% | 23% | 5% |

summative assessment. Virtual laboratories can be used to emulate the activities, concepts and questions students will face in an actual laboratory and thus provide a tool for preparation so they get more out of valuable time on the equipment. The combination of real and virtual laboratories also draws students' attention to the differences between theory and practice. Student evaluation has reinforced the efficacy of the approach.

The final contribution of the paper is to discuss practical issues of developing virtual laboratories. This paper has proposed the use of MATLAB/SIMULINK GUIs. The creation of GUIs with very similar interfaces and inputs to the actual hardware is a relatively straightforward coding exercise using the GUIDE tool, especially as most systems and control engineering staff have some proficiency with MATLAB. This has the advantage that virtual laboratories can be created relatively quickly. A second advantage of this proposal is that many Universities provide site licenses and thus student access is straightforward.

# Using MATLAB GUIs to improve the learning of frequency response methods

R.J.Mitchell
School of Systems Engineering
University of Reading
Reading, UK
r.j.mitchell@reading.ac.uk

*Abstract*—**This paper describes two MATLAB GUIs that have been designed to improve student learning of frequency response methods. One GUI is focused on plotting using asymptotes and one on systems identification. The paper includes positive student feedback on how they felt these GUIs helped their understanding, and useful suggestions on how they can be improved.**

***Keywords- Education, Frequency Response, Bode diagrams***

## I. INTRODUCTION

A recent survey of Control curricula[1] in the UK reaffirmed that Frequency Response methods were an integral part of the degree, typically taught as part of the second course in control. In the past, as shown by books such as Atkinson[2], much emphasis was given to the calculations for plotting and designing using Bode and Nyquist diagrams. Nowadays, programs such as MATLAB can do much of the work for students, but there is the danger that students do not fully understand what is happening. In [1] specific views are given:

"Today however the scenario is different. Students need to have an understanding of how to sketch Bode and Nyquist plots and root-loci, but need to have less concern for computing the numerical details; software can be used."

"I think there is great value in teaching the theory of Bode diagrams and Nyquist plots. This provides the basis of understanding the plant dynamics and the effects of closed loop control and the controller settings. However, although I think students should understand the mechanics of calculating the frequency response of a system, the use of MATLAB should enable the calculations to be done quickly so that time can be devoted to controller design. It would also allow higher order systems to be investigated."

"Computer assessment using MATLAB looks interesting … though still have a hankering after asymptotic Bode sketches as a first start - confirm with MATLAB once or twice then leave it to computer."

This year, after a teaching review, a System Identification and Control module was formed, for which the author gave ten lectures and two assignments on frequency response methods. These covered plotting Bode and Nyquist diagrams, and the design of controllers and identification of linear systems using frequency domain data.

This paper describes the assignments set, to students taking Cybernetics, Robotics and Electronic Engineering degrees at Reading, including the use of two MATLAB GUIs developed to assist students to learn about the plotting and identification, and the associated programming of controllers.

These GUIs involve the use of asymptotes, as they help the understanding of Bode diagrams, for which the author has developed extra asymptotes to help as regards phase plots. These extra asymptotes are also described.

The paper is organized as follows. In the next section, some comments are made as regards frequency response, asymptotes and identification using Bode plots. Section III describes the GUI used for plotting asymptotes and Section IV the GUI for identification. Section V contains details of the assignments, and in section VI student feedback on the GUIs is given. Section VII has the author's reflections on the feedback, and then concluding remarks are made.

## II. ON FREQUENCY RESPONSE

The frequency response of a system is the variation of its gain and phase as the angular frequency ω of its sinusoidal input is varied. The results can be plotted on Bode diagrams, where log(gain) and phase are plotted separately against log(ω), or on a Nyquist diagram, where the gain and phase provide the polar coordinates of the locus. In this paper, Bode plots are considered, which are used to plot the 'open loop' transfer function (that round the feedback loop), to assess stability, design controllers and for identification.

Here, linear systems are modeled as a series of single or quadratic poles or zeros, operating around corner frequencies. Knowing these corner frequencies, it is possible to calculate values so as to sketch the Bode plots. Similarly, the corner frequencies can be estimated from the Bode plots of a system. In both processes one considers what happens at low frequencies and then at each corner frequency in turn, until the highest corner frequency has been processed. It is thus appropriate to develop computer based systems for both the plotting of Bode plots and system identification from Bode plots.

In Thorne[3], laboratory practicals are described in which students learn to identity systems comprising multiple quadratic poles only. Thorne also believes that identification helps students in the understanding of Bode plots.

978-1-4673-1560-9/12/$31.00 ©2012 IEEE

Bode plots can be approximated by straight lines, the asymptotes, which can be derived from Bode's fundamental work[4]. For a stable minimum phase system with transfer function P(jω), its phase at $\omega_c$ is given by (1): $u = \ln(\omega/\omega_c)$

$$\angle P(j\omega_c) = \frac{1}{\pi}\int_{-\infty}^{\infty} \frac{d|P(j\omega)|}{du} \ln\coth\frac{|u|}{2}\, du \qquad (1)$$

By assuming that the gain is constant around $\omega_c$, the derivative tern can be brought outside the integral. The remaining integral evaluates as ½ $\pi^2$. Changing the derivative variable from u to ω, (1) can be rewritten as:

$$\angle P(j\omega_c) \approx \omega \frac{d|P(j\omega)|}{d\omega}\Big|_{\omega_c} * \frac{\pi}{2} \qquad (2)$$

Hence the Bode gain plot can be approximated as straight lines, between the corner frequencies of P(jω), whose gradients are integers, and the phase plot can be approximated as constant integer multiples of ½ π radians (or $90^O$).

Sketches of gain plots start and end on the first and last asymptotes, and can be close to all the asymptotes, depending on the proximity of the system corner frequencies. This is less true of the phase, due to step changes of the asymptotes at the corner frequencies. As such, books like Dorf and Bishop[5] or Nise[6] suggest that these phase asymptotes should be joined by 'diagonal' asymptotes between one tenth of and ten times the associated corner frequency, that is over a range of 100 rad/s. The author has developed a better approach, where the range for such diagonal asymptotes is set so that their slope equals that of the phase plot at the corner frequency. For a single pole or zero, this range is $e^{\pi} \approx 23$rad/s. For a quadratic pole or zero with damping ratio ζ, the range is $e^{\zeta\pi} = 4.8$ rad/s if ζ = 0.5 or 2.2 rad/s if ζ = 0.25. These values and the approach are justified in the appendix, and used in the GUIs.

Consider the following system which illustrates these extra asymptotes, and the approach for plotting and identification. The system being analysed is

$$\frac{50(1 + s/2)}{(1 + s/0.07)(1 + s/0.4)(s^2/20^2 + 0.6s/20 + 1)} \qquad (3)$$

By inspection the corner frequencies are 0.07, 0.4, 2 and 20 rad/s. The gain asymptote has value 50 and slope 0 until 0.07 rad/s, the slope is -1 until 0.4 rad/s, -2 until 2 rad/s, -1 until 20 rad/s and -3 thereafter. In these ranges, the phase asymptotes have values 0, -90, -180, -90 and -270 degrees. The range of the extra phase asymptotes around each corner frequency is 23 rad/s except at 20 rad/s where it is 2.6 rad/s. These can be seen in Fig 1, where the actual Bode plot is also superimposed. The gain plot is easy to sketch from the asymptotes. The extra phase asymptotes make it easier to sketch the phase plot.

As regards identification, the shape of the phase plot here could be used. As the phase moves from $0^O$ past $-90^O$ it is apparent that there are two low frequency poles. The phase then rises, suggesting a zero, and then the phase decreases more rapidly towards $-270^O$ suggesting a quadratic pole: the steepness of the plot at this point, which is consistent with the diagonal asymptote, suggests that the pole is underdamped.

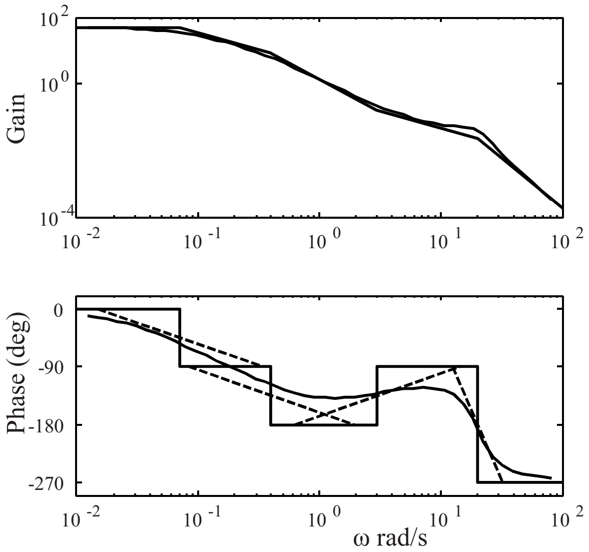

Figure 1 Bode plot of example system including asymptotes

In this example, the corner frequencies are well spaced, making sketching and identification easier as each pole or zero has a relatively small impact on the others. In the GUI described later, it is shown how closer poles and zeroes are addressed, for instance, by identifying two such poles by a quadratic pole, or a pole near a zero by a lead-lag element. First, however, the GUI for plotting is described.

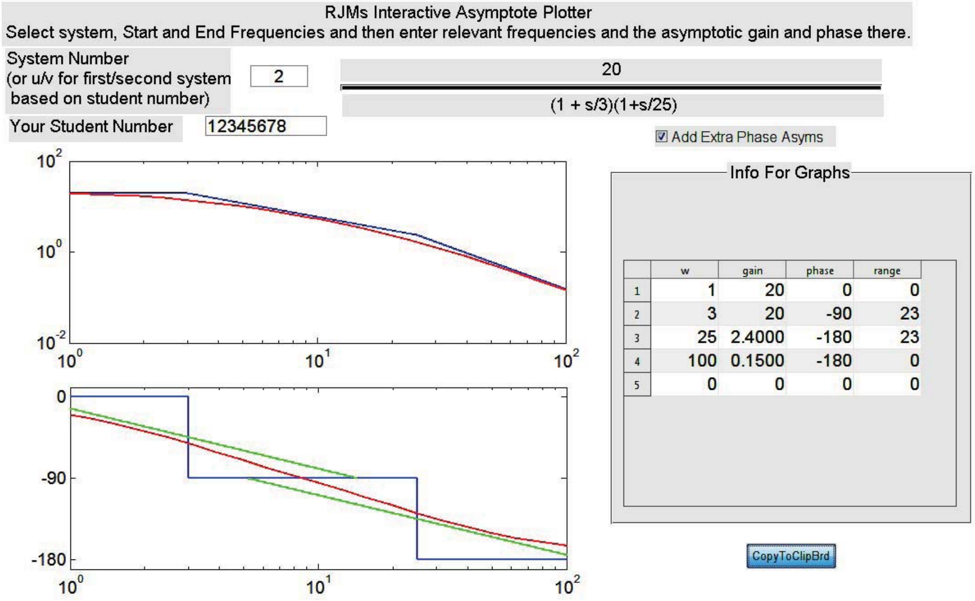
## III. GUI FOR PLOTTING

The first GUI is aimed at helping students to understand the frequency response, by drawing the asymptotes for the Bode gain and phase plots. In the lectures various transfer functions are discussed and the corner frequencies identified. It is stated that the slope of the gain asymptotes are integers and that the phase asymptotes constant values being that slope multiplied by $90^O$. It is explained that, for example, when the corner frequency is that of a single pole, the slope decreases by 1, and hence there is thereafter an extra $90^O$ phase lag. In the past, the emphasis has been on sketching gain asymptotes approximately using these integer slopes. However, in the author's experience, even some of the better students did not appreciate what was happening: this is consistent with[1].

The GUI was therefore designed to require the students to inspect a transfer function and enter each corner frequency in turn and relevant information about the gain and phase.

Initially it was planned that the students would enter the slope of the gain plot and the asymptotic phase immediately after each corner frequency. However, as phase is the gain slope times $90^O$ it was perhaps redundant to require both. The author thought that students would learn more if they had to enter at the corner frequency the asymptotic gain there as well as the asymptotic phase. Thus if the gain was G at corner frequency $\omega_1$, after which the slope was s, then at the next corner frequency $\omega_2$ they would have to calculate the gain as

$$G * \left(\frac{\omega_2}{\omega_1}\right)^s \qquad (4)$$



RJMs Interactive Asymptote Plotter

Select system, Start and End Frequencies and then enter relevant frequencies and the asymptotic gain and phase there.

| | w | gain | phase | range |
|---|---|---|---|---|
| 1 | 1 | 20 | 0 | 0 |
| 2 | 3 | 20 | -90 | 23 |
| 3 | 25 | 2.4000 | -180 | 23 |
| 4 | 100 | 0.1500 | -180 | 0 |
| 5 | 0 | 0 | 0 | 0 |

Figure 2 Plotter GUI after student has used system

Overall, when given a transfer function, the student first has to enter a suitable range of frequencies for the plot, being before the first and after the last corner frequencies. The student then enters for this first frequency, each corner frequency in turn, and the last frequency, the gain of the asymptote there, and the asymptotic phase after that frequency. If the extra diagonal asymptotes are used, the student has to enter the range of the phase asymptote around that frequency.

As each frequency is added, the asymptotes up to and including this frequency are shown. The student can move to the next corner frequency, or 'undo' the last entry.

At the end, the actual Bode plots are superimposed on top of the asymptotes, and the student can assess how well they have entered the data. As an example, suppose the system is

$$\frac{20}{(1 + s/3)(1 + s/25)} \tag{5}$$

The corner frequencies are 3 and 25 rad/s, and so a suitable range of frequencies is 1 to 100 rad/s. The student should then enter the following (the last column being needed for the extra phase asymptotes)

| ω | Gain | Phase | Range |
|---|---|---|---|
| 1 | 20 | 0 | 0 |
| 3 | 20 | -90 | 23 |
| 25 | 2.4 | -180 | 23 |
| 100 | 0.15 | -180 | 0 |

Figure 2 shows the GUI after these data have been input.

The GUI has a variety of systems built into it which the student can be tested upon. In addition, as the GUI is used as part of marked coursework, potential plagiarism needs to be addressed. Thus the GUI can also be invoked with systems whose structure is fixed, but whose corner frequencies are calculated from the student's unique student number.

## IV. GUI FOR IDENTIFICATION

For identification, the process is straightforward, with the result being built up as a series of elements starting at low frequencies, and continuing until after the last corner frequency is found. The user selects that the next element is a constant gain, an integrator, a single pole or zero, a quadratic pole or zero, or a lead-lag element.

For any system to be identified, three arrays are provided, having a series of angular frequencies and the gain and the phase at each of these frequencies. In the identification process, two more gain and phase arrays are calculated: one set has the gain and phase of the identified model, and one has the gain and phase of the model that is still to be identified. The former set is initialised with gains of 1 and phases of 0; the latter set is initialised with the original gain and phase arrays provided.

Once an element of the system model is estimated, the gain and phase of that element are calculated at each of the angular frequencies. The 'already identified' gain array is multiplied by the gain found, and its phase array has the new phase values added. The 'to-be-identified' gain array is divided by the gain found and its phase array has the new phase values subtracted.

Two Bode plots are provided. One shows the frequency response data provided, superimposed on to which is the estimate of the system so far. The other has the response yet to be identified. The user interacting with the system should see the identified system following the original plot at lower frequencies. Deviations of the to-be-identified plot from its low frequency response are used to identify the next element.

As used this year, in the GUI the user specifies the type of element, and the system automatically estimates the parameter(s) associated with that element, such as gains or time constants, which the user can accept, modify or reject. In the final section of the paper consideration is given as to how the user could be required to calculate these parameters.

Gain is 0.70711 at 0.040168

System est as 8.9973 / (s*24.8955 + 1)

Figure 3 Part way through identification of two pole system

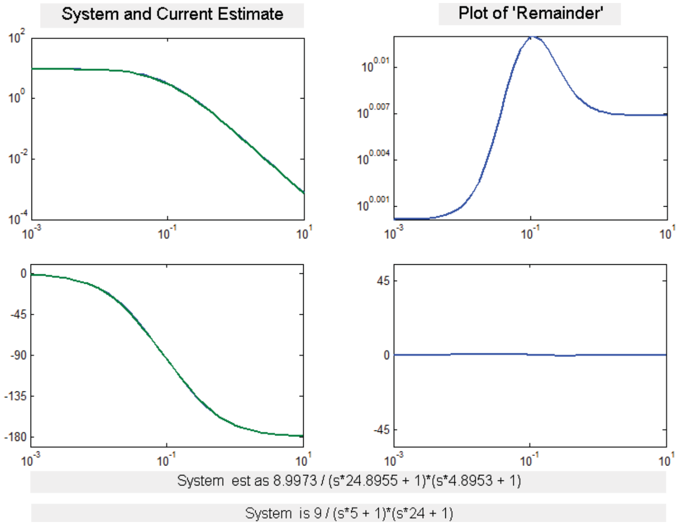
When the user selects the type of the next element, the plots are updated and the user is shown the value of any estimated parameter. The user can then modify that value, perhaps on the basis that a subsequent element is affecting this one. The user can then accept the element and value, or cancel, which could happen if the wrong type of element had been selected.

The system estimates the gain of an element from the first value in the gain array. For a pole or zero, the user specifies whether its time constant is found using the gain or phase array. If the former, the time constant is the reciprocal of the angular frequency where the gain is a factor 0.707 away from the low frequency gain; if the latter the frequency where the phase is $\pm 45^{O}$ is used. For quadratic poles or zeros, the frequency where the phase is $\pm 90^{O}$ gives the estimate of $\omega_n$ and this value and the gain there give an estimate of $\zeta$. If $\zeta > 1$, the result is shown as two time constants. This allows the user to identify two close poles or two close zeros as one element. When a pole and a zero are close, a lead-lag element can be identified: the frequency where the phase is a local minimum or maximum, and the value of that phase are used to find the time constants.

Fig 3 shows the GUI part way through the identification of a system with two poles. Here the gain was first estimated, as 8.9973, the actual value is 9. Then the time constant of the first pole was found, estimated at 24.895: it should have been 25. The graphs on the left show that this model accurately follows the actual plot at low frequencies. The graphs on the right indicate that a further pole needs to be identified.

At the end, the student presses the reveal button and the actual transfer function is given. The student can then see how well the process has worked by comparing the actual and estimated transfer functions and Bode plots.

Fig 4 shows part of the GUI at the end of identifying the two pole system. The second pole should have had a time constant of 5, but the estimate was 4.65. The remainder plots are not quite horizontal lines showing that there have been small (but expected) errors in the estimates of the parameters.



System est as 8.9973 / (s*24.8955 + 1)*(s*4.8953 + 1)

System is 9 / (s*5 + 1)*(s*24 + 1)

## V. Assignments

These GUIs were used in two assignments. The first was aimed at familiarizing the student with frequency response plots. It comprised tasks set after lectures 2, 3 and 4, including the use of the GUI to plot various systems, and to design a simple controller and assess its performance. Formative feedback only was provided for this part.

The first task was to call the m file provided which generated a system based on the student's username: the numerator and denominator polynomials were displayed symbolically, as shown at the top of Fig 2. Students then noted the corner frequencies of that system, and used MATLAB to calculate the gain and phase at those frequencies. In the second task, students used the GUI to plot a few different systems, including one based on their username. Finally, the students used MATLAB to design a proportional controller to achieve a phase margin specification, plot the step response and calculate key values such as overshoot and time to peak.

Students were provided with a word document into which results were to be pasted, with questions asking the student to reflect on their answers, provide the lecturer with feedback on the GUI and say whether they felt it useful to teach asymptotes. Built into this document were options for formative assessment of the work – such as the section was missing, wrong, partially correct or correct. The marker could quickly circle the appropriate assessment and, with more detailed comments, provided rapid and relevant formative feedback on this part of the assignment, which are known to be beneficial [7], [8].

The second assignment included more plotting, of systems with second order poles, the use of the identification GUI, and the design of Phase Lead, P+I and PID controllers using frequency domain data. For the design, students were provided with an m file with functions provided for defining systems, for plotting graphs, and empty functions for controller design which the students had to complete. Again results, and code, were pasted into a word document, but this now had a marking scheme instead of comments like 'wrong'. Students were also asked to comment on the GUI.

## VI. Evaluation

The 20 students on the module generally did the first assignment well: the two who did not cited difficulties understanding the GUI. Most answered the questions asked.

The first question asked was: 'Has the GUI helped/hindered you to understand asymptotes/Bode plots". Almost all students said it had. Some specific quotes are given below:

"At first I felt the GUI was hindering me as I could not work out how to get the correct asymptotes, however the GUI started to encourage me to research and learn the theory … Looking back on the learning process I feel it was very useful for understanding the concepts of asymptotes and Bode plots".

"The GUI has vastly improved my understanding of Bode plots, mainly due to it being a focused exercise towards improving sketching Bodes that includes being able to check answers against the actual plots of the system".

The second question asked if it would have been better if they had been asked to specify the gain slopes rather than the value of the asymptotic gain at the corner frequencies. Many students said that would have been easier, but they would not have learnt as much. Some specific quotes are given below.

"I have previously used the method 'slope specification' when plotting by hand so it is useful to have another method."

"I feel if I had learnt both and tried both on a similar style GUI I would have learnt far more. It would have been useful to practice both methods so that we could work out which method suited us individually."

"I don't think that I would have learnt so much if I had to only enter the slopes"

The third question was whether it was useful to teach asymptotes . All who expressed a preference believed it was.

"It is very useful teaching about asymptotes because the process of plotting them enables one to understand how the various terms of a transfer function relate to the system's gain, phase and corner frequencies. Without the manual plotting of asymptotes I don't believe that my understanding of Bode plots … would be nearly as in depth"

"[Definitely] as it offers a basis for Bode plots without having to do thousands of calculations. … It helped me a lot in understanding Bode plots."

Students were also asked to make suggestions for improving the GUI. On-line help was requested, and there were specific comments on the entry of data at each corner frequency in the plotting GUI. These will be used next year.

For the second GUI students were asked if it helped/ hindered understanding. Again almost all students felt it did.

"I found the GUI extremely helpful as I was able to see what is happening with the frequency response of the system when different terms to the transfer function are added. [Now] I definitely feel more confident about Bode plots"

"The System Id GUI has helped most of all in understanding the estimation of the composition of transfer functions …. The values of each of the elements of the transfer function, which are generally estimable via the analysis of the angular frequency at which changes in the bode plot occur, were an element … that the author had not fully appreciated in the past. Being able to, at a glance, agree or disagree with the value presented in the estimation was helpful"

## VII. Reflection

The students believe that both GUIs have helped them understand the material, and they agreed that teaching asymptotes was beneficial. Although the GUIs were demonstrated in lectures, some difficulties were found, so more help will be given next year as regards the use of both GUIs.

It was interesting to see the comment that it would be more useful to have initially been asked to specify the slope of the gain after the corner frequencies and in later examples to give the value of the gain asymptote at the corner frequency. The first method could be used in familiarization.

Reflecting on this the author realized that for the identification GUI students specified an element type and the system automatically calculated the associated element parameter(s), whereas the plotting GUI expected the student to do relevant calculations. This was inconsistent.

Hence for next year, for the plotting GUI, initially users will enter slopes to specify gain, and later the asymptotic gain at the corner frequencies. Also, the identification GUI will have two modes, one where the parameters are found automatically, and one where a hint is given and the user has to then calculate the parameter. For instance, for a lead-lag element the hint will give data where the phase is a local maximum/minimum using which the student will calculate the two time constants.

## VIII. Conclusion

Two useful GUIs have been produced which the students believe have helped their understanding of frequency response methods. Student feedback is also influencing the development of the GUIs so that next year there will be a better combination of automatic and student-based calculations.

## Appendix

This appendix contains the derivation of the range of frequencies around the corner frequency for the extra 'diagonal' phase asymptotes. Conventionally this range is recommended as 100 rad/s [5], and Fig 5 shows these, and the actual phase, for both a single pole and a quadratic pole with damping ratio 0.5.

For a single pole, this approach is quite good, as the area of the region on one side of the asymptote is approximately equal to that on the other. However for a quadratic pole the areas are quite different. A better approach, advocated here, is for the slope of the diagonal asymptote to equal that of the slope of a pole or zero at the corner frequency.

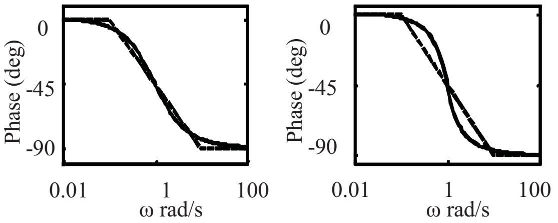

Figure 5. Phase and Asymptotes for Single and Quadratic Pole

As regards, finding the diagonal asymptote, let r be the range over which the diagonal asymptote spans, centred on the corner frequency, $\omega_{CF}$, of a single or a quadratic pole or zero, which changes the phase by nπ. If φ is the phase of such an element, plotted against log(ω), the slope of the asymptote is set by the slope of the element evaluated at $\omega_{CF}$, so

$$\frac{n\pi}{\log(r)} = \left.\frac{d\varphi}{d\log(\omega)}\right|_{\omega_{CF}} = \left.\frac{\omega}{\log(e)}\frac{d\varphi}{d\omega}\right|_{\omega_{CF}} \tag{6}$$

This can be rearranged to give

$$r = e^{n\pi \Big/ \left.\omega\frac{d\varphi}{d\omega}\right|_{\omega_{CF}}} \tag{7}$$

For a single pole or zero, with time constant T, n = ± 0.5 and $\varphi = \pm\tan^{-1}(\omega T)$,

$$\left.\omega\frac{d\varphi}{d\omega}\right|_{\omega_{CF}} = \pm\left.\frac{\omega T}{1+\omega^2 T^2}\right|_{\frac{1}{T}} = \pm\frac{1}{2} \tag{8}$$

$$r = e^{\pi} \tag{9}$$

For a quadratic pole or zero with corner frequency $\omega_n$ and damping ratio ζ, for which n = ±1, it can be shown that

$$\left.\omega\frac{d\varphi}{d\omega}\right|_{\omega_{CF}} = \pm\left.\frac{\omega\, 2\zeta\omega_n\left(\omega_n^2+\omega^2\right)}{\left(\omega_n^2-\omega^2\right)^2+4\zeta^2\omega_n^2\omega^2}\right|_{\omega_n} = \pm\frac{1}{\zeta} \tag{10}$$

$$r = e^{\pi\zeta} \tag{11}$$

Fig 6 shows the phase and these asymptotes for a single and quadratic pole, using these values of r. The phase is easier to sketch than the conventional approach. Instead of crossing the diagonal asymptote and then intersecting with it at the corner frequency, the actual phase moves smoothly between the horizontal asymptote before or after the corner frequency (at some integer * ½ π) and the diagonal asymptote. The gain curve moves between asymptotes in a similar manner.

*Abstract*-**Teaching engineering concepts using demonstrations and experiments on real hardware is always engaging and well received by students. This paper provides reference materials (both theoretical and test results), to be used in Control teaching and assessment using a laboratory experiment, with a real-time single board computer based robotic vehicle (National Instruments Robotics Starter Kit). This robotic vehicle is programmed using a graphical programming environment. The Adaptive Cruise Control (ACC) algorithm based on Proportional-Integral (PI) and Proportional – Integral – Derivative (PID) Control are deployed on a field programmable gate array (FPGA), included in the robot's architecture. The robot model (based on a given second order transfer function) is controlled using the same method. The results obtained are compared for the simulation model and a real robot. The performance comparison demonstrates a good correlation between theory and implementation, whilst demonstrating problems and discrepancies introduced by a real system.**

***Keywords: System modelling,* Adaptive Cruise Control (ACC), *PID Controller, Educational robotics, Real-time implementation, Single board computer, FPGA programming.***

## I. INTRODUCTION

Lately, Engineering at Kingston University London has been running a project to develop new Electronics and Control teaching methods. As a result, simulation is not the tool of choice for this task any more. The applied approach to teaching and learning, using latest technology is gaining popularity and interest in the faculty.

This paper proposes an experimental method for teaching control concepts to senior undergraduate engineering students and then assessing the learning by setting a group assignment with the objective to design and implement the software to control the performance of a robotic vehicle with on board Adaptive Cruise Control (ACC), implemented using a PI and a PID loop. Graphical programming language (LabVIEW) was used for code implementation, as it does not deter from the main learning goal by enabling a quick completion of the programming task, allowing students to focus on tuning and testing. The target hardware was a Starter Kit Robot from National Instruments; where two robots were used as 'the leader' and 'the follower'. ACC [1], [2] was used to maintain a set distance between them. These experiments not only illustrate the theoretical concepts but also offer an excellent opportunity for students to programme a real-time, single board computer by directly accessing on-board FPGA, which is likely to open new opportunities for final year project implementation.

The teaching methodology, overall teaching plan (including the formal lectures on control design for distance tracking based on the classical controllers [3], hands-on exercises, and associated assessment task) are presented in Section II. The rest of the paper provides all of the information required by instructors for course delivery, including the solution of the assessment, as follows. Section III describes the hardware and associated system transfer function (given to students), while Section IV deals with the theoretical concepts required. Section V deals with system test, offering all of the results required by the instructor. Section VI discusses the design, tuning and testing of a performance of classical controllers, implemented in ACC. Overall, it verifies the correlation between theoretical expectations and real-life system performance.

## II. UNDERLYING TEACHING STRATEGY

This course is aimed at senior undergraduates, who have moved on from the 'system approach' used in first year to more 'discrete' learning. In year two they study particular concepts, in order to acquire sufficient knowledge in a range of disciplines (programming, electronics and control). They can then amalgamate these concepts and work for the first time with a complex system, applying this knowledge and re-enforcing understanding through implementation.

Students are given a set of formal lectures, covering relevant control concepts as shown in Table I:

Partly sponsored by National Instruments

978-1-4673-1560-9/12/$31.00 ©2012 IEEE

TABLE I

LECTURE SCHEDULE AND MILESTONES

| Week | Milestones |
|---|---|
| 1 | Introduction to modelling of dynamic systems |
| 2 | Use of Laplace transform and transfer functions |
| 3 | Time and feedback domain analysis |
| 4 | Frequency domain analysis |
| 5 | Introduction to PI and PID control including PID loop tuning |
| 6 | ACC and switching rules |

This is followed by a set of tutorials and laboratory exercises as shown in Table II.

TABLE II

LABORATORY SCHEDULE, MILESTONES AND MODE

| Week | Milestones | Mode |
|---|---|---|
| 1 | Introduction to control concepts | Individual |
| 2 | PID tuning using Matlab | Individual |
| 3 | Introduction to LabVIEW and FPGA toolbox | Individual |
| 4 | Introduction to hardware, 'walk-through' exercises (NI single board RIO including FPGA module) | Group (3) |
| 5 - 6 | Implementation and testing (work on group assignment) | Group (3) |

Introduction to the software and hardware is done individually to ensure that every student gets the chance to learn the software and become equipped to work independently. However collaborative learning used in later weeks is highly beneficial when new complex concepts are to be adopted.

Student assessment task aims to:

1. Design an Adaptive cruise control algorithm using MATLAB/SIMULINK using the dynamic model of the robot (given) and obtain optimised solution using PI and PID strategy, in order to perform 'the leader' and 'the follower' action (maintain a certain distance between the leader and follower).
2. Investigate the construction and operation of the real robot, including the incorporated sensors and actuators.
3. Investigate a programming method for a real-time embedded FPGA based system.
4. Apply the Adaptive cruise control strategy developed in 1, to a real robot.
5. Compare system performance in order to discuss the correlation between theory and implementation in terms of PID tuning.
6. Compare the system performance to discuss the correlation between the performance of the robot model and a real robot. Discuss the problems and discrepancies introduced by a real system.

In addition to the written report including the graphs (similar to the ones shown in Sections IV and V), a demo and a viva are also introduced as part of the assessment, to identify the level of learning for individuals and curb plagiarism. Additional benefits of this assessment task are development of 'soft skills' including teamwork, project management and public speaking, with the added benefit of peer support.

## III. HARDWARE CHARACTERISTICS AND SYSTEM TRANSFER FUNCTION

The LabVIEW starter kit robot (Fig. 1) is based on a NI single- board RIO, with Ethernet connectivity. The robot 'follower' uses ultrasonic sensors for velocity and distance tracking of the 'leader' (2cm - 3m sensor range) and two 12V DC brushed motors, (linear velocity of approximately 0.9 [m/s]). The robots can be programmed either by using the high-level LabVIEW robotic starter kit API or by using the LabVIEW FPGA module [4].

The robot model transfer function approximated through the model identification process can be presented as:

$$\frac{v}{v_{sp}} = \frac{1}{0.48s^2 + s + 1} \tag{1}$$

where $v$ and $v_{sp}$ respectively denote the robot's velocity and velocity setpoint. Units are in [m/s].

Fig.1. NI LabVIEW starter kit robot [4]

## IV. CONTROL DESIGN

The Adaptive Cruise Control is based on two controllers; Proportional-Integral-Derivative (PID) control for velocity tracking, and PI control for distance tracking. The distance tracking controller calculates the velocity setpoint using the difference of the current inter-distance between the leading and following robots from the desired distance-headway. The velocity tracking controller computes the velocity setpoint, to maintain the constant desired cruising speed. ACC concept will be discussed in the next section, after tuning of the PID parameters.

### A. PID parameters

The PID controller defined in the FPGA module has the configuration illustrated in Fig. 2. The controller adjusts the speed of the DC motors (in the robot) based on the given set-point speed. The gains of the PID control are set to zero by default; therefore the set-point speed will be directly sent to the DC motor. In this work, we design our controller to calculate the set-point speed which can fulfil the requirement of the ACC system.

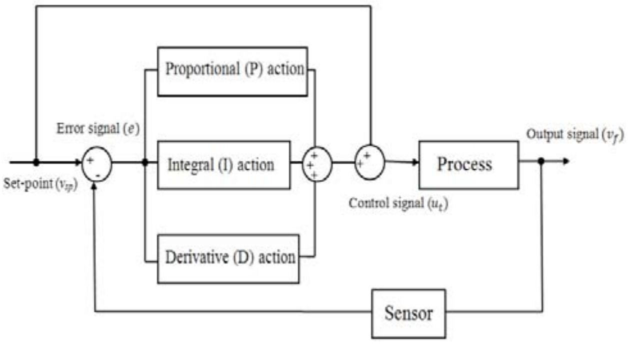

Fig. 2. Configuration of the controller including PID control in the FPFA

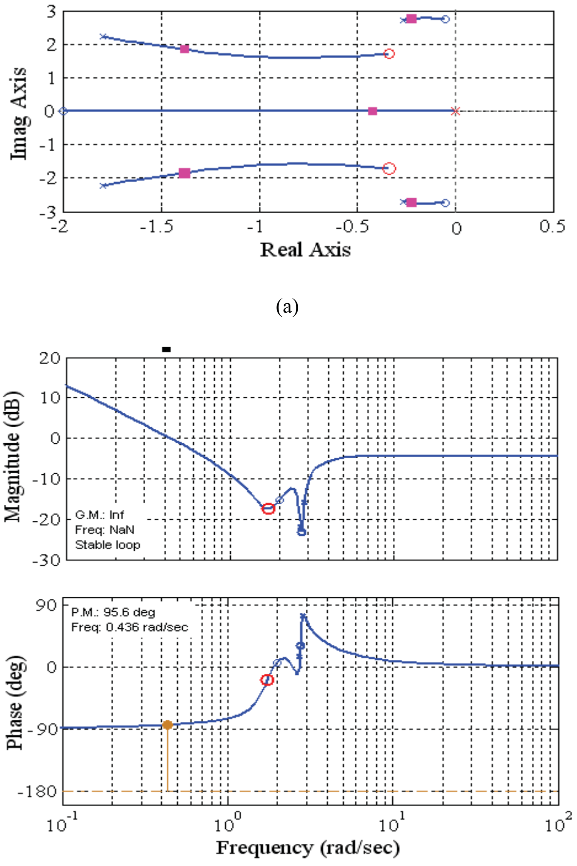
Different tuning rules to obtain the Proportional-Integral-Derivative (PID) control gains were introduced in literature [5]; such as, step response (frequency response method), Ziegler-Nichols etc. “Control and Estimation Tools Manager” toolbox in MATLAB/SIMULINK [10] is used. to tune the PI/PID controllers. By using this toolbox, students can easily design the controllers through the interactive plots such as root-locus, Bode, or Nichols, within the SISO design tool. The controller can be graphically tuned by manually moving, adding, or deleting poles and zeros of the model’s tunable blocks, and observing the closed loop response of the system in the analysis plots such as, step response, impulse response, pole/zero response etc. Root locus and open-loop bode diagrams resulted from the tuning process are illustrated in figure 3. These results were obtained using the Control and Estimation toolbox for a single-input-single-output system and selecting singular frequency based tuning for the tuning algorithm. PID controller gains for the three controllers, used for an ACC system, are given in Table III.



(a)

(b)

Fig. 3. (a) Root locus for open loop system, (b) Open-loop bode diagram

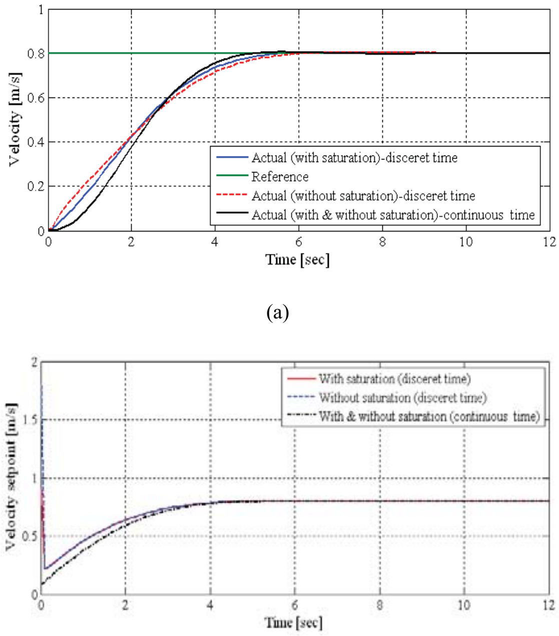
TABLE III

DISCRETE TIME PID CONTROLLERS' GAINS

| | $k_p$ | $k_i$ | $k_d$ |
|---|---|---|---|
| Default PID controller | 0 | 0 | 0 |
| Distance Tracking (ACC) | 0.9 | 0.5 | 0 |
| Velocity Tracking (CC) | 0.2 | 0.48 | 0.2 |

The closed-loop responses of the system given by Eq.1 are presented in Fig. 4. The responses of the closed-loop system in both continuous-time and discrete-time have been compared. The control action (velocity setpoint $v_{sp}$) has to be constrained between [0,0.9], reflecting the physical limitation of the system i.e. motor velocity. The results obtained by saturating the control output have been compared to those without saturation, as illustrated in Fig. 4. Fig. 4. (b) shows that the control action initially violates the upper bound limit if it is not constrained. In most of the system, saturation can degrade the performance, especially when using the PID controller.

This is due to a phenomenon called "integrator windup" which causes a large overshoot in response. To solve this, an anti-windup can be used. Since there was not any serious issue in our design, we did not use anti-windup.



(a)

(b)

Fig.4 (a) the closed-loop responses of the system given by Eq.1 (b) using continuous-time and discrete-time PID controllers, (b) the control actions

## B. ACC switching rules – distance (ACC) and velocity (CC) tracking

ACC systems operate in two different modes depending on the situation in the front - distance tracking or velocity tracking. If the ultrasonic sensor of the follower (ACC equipped) detects any obstacle, or a slower moving robot in front, the controller adjusts the velocity to maintain the clearance inter-distance (desired distance). If the inter-distance measured by the ultrasonic sensor is greater than the desired distance, it will switch to velocity tracking mode, known as cruise control (CC) mode, to track the desired velocity.

The switching logic was devised to implement automated switching between the two modes of operation for the ACC system, i.e. velocity tracking (CC) and distance tracking [3], [6], [7]. The switching rules for transition between CC and ACC modes are illustrated in Table IV.

TABLE IV

LOGICAL RULE FOR SWITCHING BETWEEN CC AND ACC (Shakouri, Ordys and Laila, et al. 2011)

| | $v_f < v_{des}$ | $v_f \geq v_{des}$ |
|---|---|---|
| $d < d_{des}$ | ACC | CC |
| $d \geq d_{des}$ | CC | CC |

A schematic block diagram of this switching algorithm is underlined in close-up of the switching logic CC/ACC in Fig. 5.

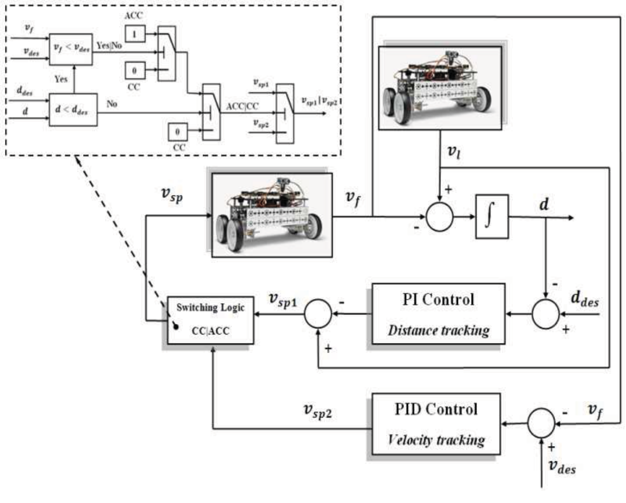


Fig. 5. A schematic block diagram of an ACC system developed in the simulation including a PI control for distance tracking and a PID control velocity tracking.

The desired headway distance $\boldsymbol{d_{des}}$ can be computed using the equation (2), assuming that the follower and leader robot have the same speed ($v_f = v_l$), known as Constant-Time Headway policy [8], [9]:

$$d_{des} = \underbrace{l + d_s}_{d_0} + T_h v_f \qquad (2)$$

*l*- robot length, $d_s$ - additional distance between two robots, $v_f$ - follower robot's velocity and $T_h$ is the constant-time headway (approximates system reaction time) [s].

Distance between real robots is measured by an ultrasonic sensor. In simulation, the distance is determined by taking the integral of their relative velocity:

$$d = \int_0^t (v_f - v_l)dt \qquad (3)$$

The Schematic block diagram from Fig 5, implementing ACC in LabVIEW is shown on Fig. 6.

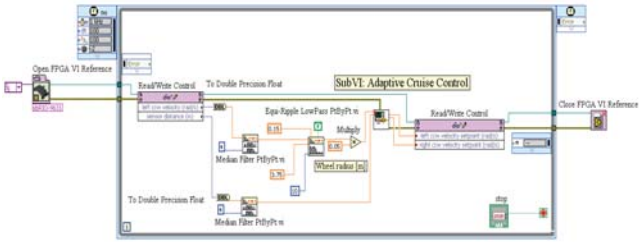

Fig. 6. The configuration of the LabVIEW block functions for implementing the ACC on a robot

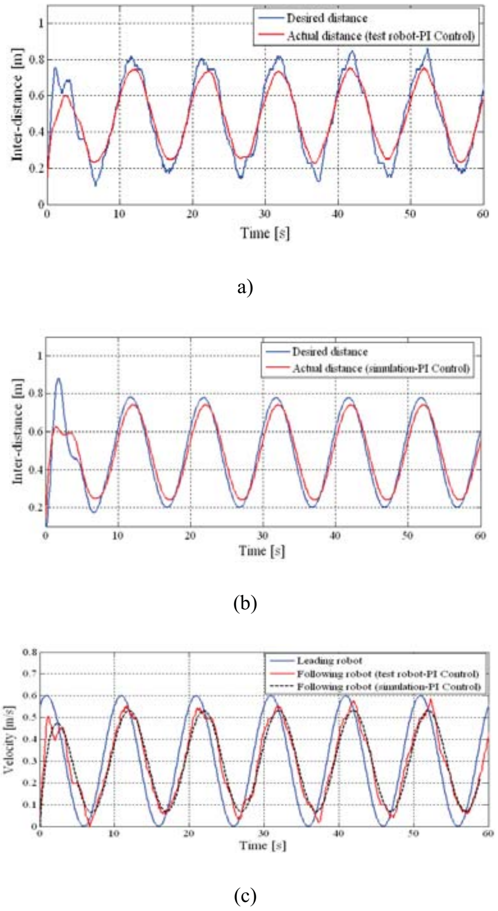
## V. Testing and Results

The ACC system was developed and tested using Matlab for PID tuning and LabVIEW for hardware implementation. The programming of the controller has been implemented in LabVIEW MathScript Node. The ACC system was designed and tested in the simulation and implemented on the robot's LabVIEW FPGA module, for comparison. In the initial experiment the leader robot is virtualised, the sinusoidal signal represents the leader robot's velocity and the distance between robots can be calculated from Eq. 8. The final stage of the test used two test robots; and the distance between them is measured by an ultrasonic sensor. The program developed in LabVIEW for real-time implementation is depicted in Fig. 6.

Fig. 7 illustrates the results for distance tracking (ACC) mode for the test executed by using the PID controller. The initial distance between the robots was setup at 0.1 [m]; both robots start from zero velocity. Based on the test, the minimum safe distance $d_o$ and time-constant headway $T_h$ were chosen to be 0.1 [m] and 1.3 [s], respectively. Some slight undulations in the results on the desired distance curve are due to the desired distance being a function of the follower robot velocity; therefore its variation depends on the velocity. However, the ACC system operates very well for distance tracking.



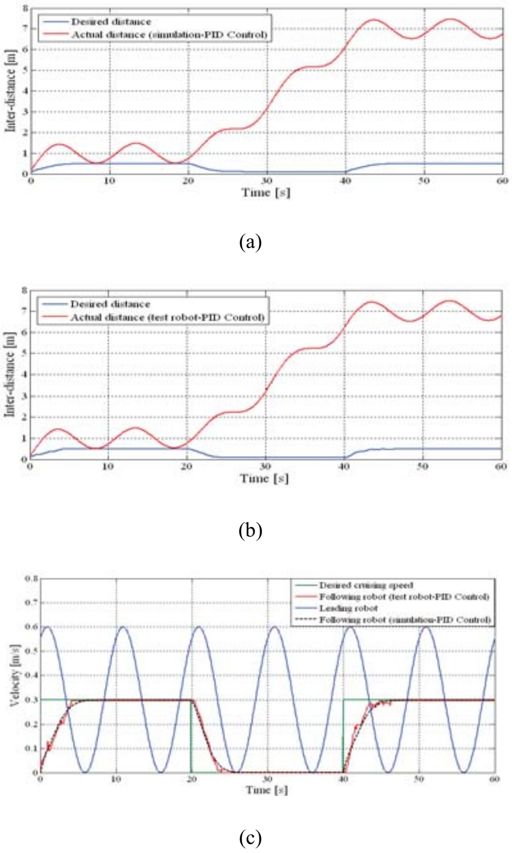
a)

(b)

(c)

Fig. 7. Distance tracking (ACC) mode using PI control- (a) The inter-distance between the robots using test robot, (b) the inter-distance between the robots from simulation, (c) the velocities obtained during distance tracking using test robot and from simulation implementation

Fig. 8 shows the results for velocity tracking (CC) mode accomplished by PID Control with the same initial conditions. However, the desired cruising speed has been selected as a step form; from 0-20 [s], the value of the desired speed is 0.3 [m/s], its value reduces to 0 [m/s] between 20-40 [s] and then it reverts to 0.3 [m/s] from 40 [s] onward. Since the actual distance is far away from the desired distance, the ACC system operates in CC mode, so that the follower robot's velocity tracks the desired cruising speed (see Fig. 8.c), rather than tracking the desired distance. Consequently, it causes the distance between the robots to be increased (see Fig. 8.a-b).



(a)

(b)

(c)

Fig. 8. Velocity tracking (CC) using PID control- (a) The inter-distance between the robots using test robot, (b) the inter-distance between the robots from simulation implementation, (c) the velocities obtained during distance tracking using test robot and from simulation implementation

## VI. CONCLUSIONS

The experiment described here delivers a range of robotics and control concepts, and control strategies, including PI and PID, PID tuning and switching strategies. It requires students to program these strategies and to implement in a real device a target real-time microcontroller board that has been configured as a robot, which is an excellent target system, capturing students' interest and imagination. This paper proposes an assessment brief for the experiment to contain:

1. System modelling and simulation.
2. Implementation in hardware.
3. Testing of the ACC system.

This paper deals with the implementation of only one type of control algorithm and there is scope to implement others e.g. fuzzy logic, or even Model Predictive Control, which can be used for post graduate level teaching. There is also potential for system hardware enhancement/expansion, to include further sensors, for example global positioning systems (GPS), inertial navigation systems (INS), camera etc. (all presently available off the shelf for the specified target board), opening a range of additional opportunities for further control feedback but also experiments and assignments in the field of digital imaging, signal processing, system fusion, robotics, autonomous driving and more.

*The teaching materials described in this paper can be made available on request to the conference participants.*

***Abstract*— Advancement in computer system hardware makes it difficult to meet the demands of teaching computer architecture and organization. Visualization of different architectures enhances the learning process among students by using simulators. This paper attempts to give a survey on the following simulators (1) Electrical Numerical Integrator and Computer (ENIAC) was the first electronic digital universal computer built at Pennsylvania University in 1944-1946., (2) The Visible Virtual Machine (VVM) based on Little Man Computer (LMC) which is general for von Newmann computer architecture, (3) MARS an Education-Oriented MIPS Assembly Language Simulator, (4) Logisim for simulating digital logic circuits and (5) SPIM for MIPS Assembly Language Simulator that are going to be taught in the course Computer Architecture and Organization by the faculty members. Also, evaluate the selected simulators according to the criteria established in the course meetings.**

***Keywords-component Computer Architecture and Organization; Simulation; Evaluation; Electrical Numerical Integrator and Computer; The Visible Virtual Machine; MARS; LOGISIM; SPIM;***

## I. Introduction

Computer-based graphical simulators are widely used in universities to support the teaching of computer architecture [1].These range from relatively simple, visual simulators to advanced, complex simulators for research and product development. One area where software simulators have become almost indispensable is in undergraduate computing courses [2].These simulators are often used to aid student's understanding of complex technologies which are difficult to conceptualize and visualize without the help of graphical animations that the modern simulators can offer [1].

Advancement in computer system hardware makes it difficult to meet the demands of teaching computer architecture and organization. Visualization of different architectures enhances the learning process among students by using simulators. Rather making a comprehensive simulator that can cater the requirement for the course, available simulators can serve the purpose as they can save time resource, ease of use, capacity to learn the concepts to fullest which are delivered in the course, can be accessed anywhere and anytime by the students. Finding the appropriate simulator for the course is a difficult task. Similar study was also conducted [3].

The paper describes the evaluation process followed before the induction of simulators in the course. The paper is organized as follows: Section II gives the teaching strategy followed in the course. Section III describes the criteria for which the simulators were selected. Section IV introduces the evaluation process. Section V describes the questionnaire design. Section VI concludes the results and Section V concludes the paper.

## II. The Teaching Strategy

There was a lack of giving students the exposure of different architectures visualization through graphical representation. Instead, they receive the theoretical aspect of internal structure and components of the computer, how the instruction are being executed and handled by different architectures. This problem can be handled by the use of simulators.

For the batch 2010, currently enrolled in their 5th Semester, the course Computer Architecture and Organization was restructured to two hours of lectures and two hours of laboratory work per week whereas before it was only three hours of lectures per week. This way the gap between theoretical and practical work was removed.

## III. Criteria for Selecting Simulators

As advised by **Chairman** *Computer Engineering Department* **Dr. Syed Misbahuddin** of *Sir Syed University of Engineering & Technology* the simulators that need to be the part of the course should possess certain properties and should be tested by the instructors before it is included in the laboratory work. The characteristics that a simulator should possess are usability, availability and topics covered in the lectures.

978-1-4673-1560-9/12/$31.00 ©2012 IEEE

## IV. Evaluation Process

Although simulator imitates a device near to reality but it is necessary to evaluate its effectiveness to which it can be inducted into the course as a teaching aid and to support the learning of the students.

### *A. Methodology*

The evaluation of the simulators was based on the criteria discussed earlier. For evaluation both qualitative and quantitative methods was used. For qualitative method Opinion survey using 5-point Likert scale and having open ended questions as well. For quantitative method describing the data numerically measure of center and location technique was used to interpret the data gathered from the survey.

### *B. Participants*

The participants were composed of eight faculty members teaching the course of Computer Architecture and organization. Among eight, two were Assistant Professors and two were Lecturers who are responsible to give lectures in the lecture room. Two Research Assistant and Junior Lecturer assisting any one of the above in the Laboratory was also included in the survey.

## V. questionnaire Design

The opinion survey questionnaire was given to the faculty members (Sample Size N=8). Each survey was conducted for each simulator making it five surveys consists of four parts. Part A consists of the information about the participant's profile; Part B consists of the information for the simulator usability and the recommendations was taken from []. Part C consists of the information for the simulator availability. Part D consists of the information relevance to the course contents covered by the simulator which was further divided into four sub categories: *Fundamentals of Computer Architecture, Memory System Hierarchy, Communication and Interfacing and Processor System Design.* Values for likert scale in the questionnaire used is as follows 1= Strongly Agree (value = 2) 2= Agree (value = 1) 3= Not Sure/Not Applicable (value = 0) 4= Disagree (value = -1) 5= Strongly Disagree (value = -2)

In the first part, questions 1 to 5 focus on the profile of the respondents. As the respondents type was homogenous so the profile was drawn with close ended questions.

In the second part, questions 6 to 19 focus on the simulator usability. This part of the questionnaire is to achieve the usability of the simulator that needs to be included in the course. To achieve information about the simulator usability the faculty members were asked to evaluate from 1 to 5 their satisfaction and the simplicity about the simulator.

In the third part, questions 20 to 22 focus on the simulator availability. This part of the questionnaire is to find out that the simulator can be used anywhere anytime and on different platforms. To achieve information about the simulator availability the faculty members were asked to evaluate from 1 to 5 their satisfaction.

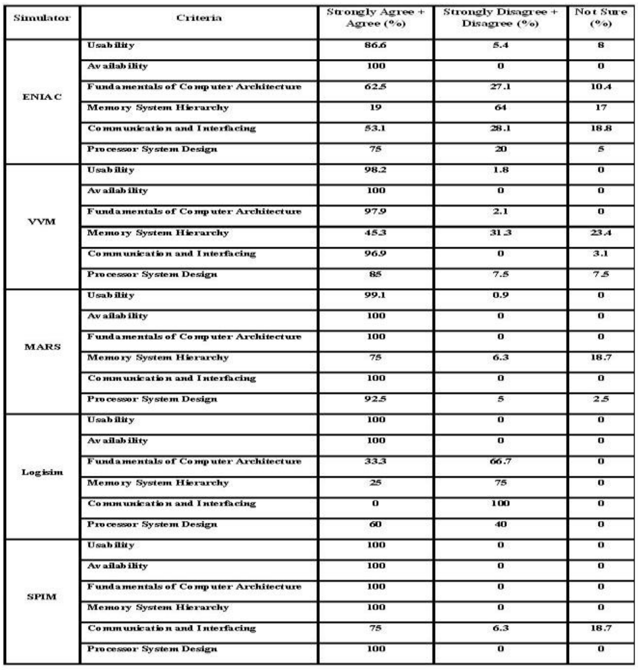
In the fourth part, it is divided in four categories related to the course contents and the topics that the simulator covers. First category *Fundamentals of Computer Architecture*, questions 23 to 28 focus on the fundamental concepts of computer architecture. To achieve information about these, faculty members were asked to evaluate from 1 to 5 their satisfaction. Second category *Memory System Hierarchy*, questions 29 to 36 focus on the performance issues. To achieve information about these faculty members were asked to evaluate from 1 to 5 their satisfaction. Third category *Communication and Interfacing*, questions 37 to 40 focus on the communication between the peripherals and interaction between the components. To achieve information about these faculty members were asked to evaluate from 1 to 5 their satisfaction. Fourth category *Processor System Design*, questions 41 to 45 focus on the substrate of processor logic implementation. To achieve information about these faculty members were asked to evaluate from 1 to 5 their satisfaction.

## VI. Results

Below are the summary of the evaluation based on the opinion survey:

### *A. Qualitative Analysis*

Five opinion surveys were conducted. All before the start of the semester and total of eight faculty members participated in the survey. Figure 1 shows the criteria on which the survey was conducted. The strongly agree/agree and the strongly disagree/disagree results are aggregated and the results are presented below



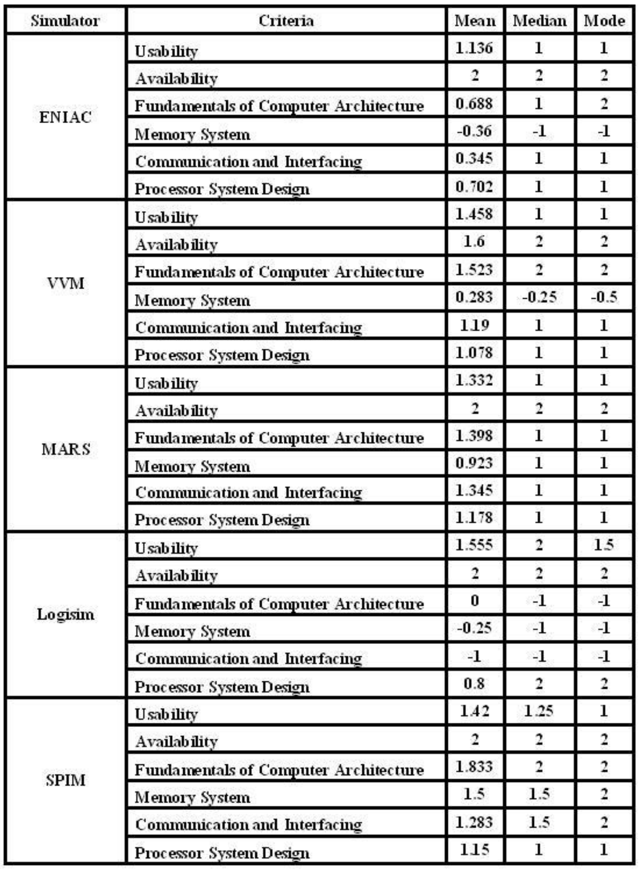
| Simulator | Criteria | Strongly Agree + Agree (%) | Strongly Disagree + Disagree (%) | Not Sure (%) |
|---|---|---|---|---|
| ENIAC | Usability | 86.6 | 5.4 | 8 |
| | Availability | 100 | 0 | 0 |
| | Fundamentals of Computer Architecture | 62.5 | 27.1 | 10.4 |
| | Memory System Hierarchy | 19 | 64 | 17 |
| | Communication and Interfacing | 53.1 | 28.1 | 18.8 |
| | Processor System Design | 75 | 20 | 5 |
| VVM | Usability | 98.2 | 1.8 | 0 |
| | Availability | 100 | 0 | 0 |
| | Fundamentals of Computer Architecture | 97.9 | 2.1 | 0 |
| | Memory System Hierarchy | 45.3 | 31.3 | 23.4 |
| | Communication and Interfacing | 96.9 | 0 | 3.1 |
| | Processor System Design | 85 | 7.5 | 7.5 |
| MARS | Usability | 99.1 | 0.9 | 0 |
| | Availability | 100 | 0 | 0 |
| | Fundamentals of Computer Architecture | 100 | 0 | 0 |
| | Memory System Hierarchy | 75 | 6.3 | 18.7 |
| | Communication and Interfacing | 100 | 0 | 0 |
| | Processor System Design | 92.5 | 5 | 2.5 |
| Logisim | Usability | 100 | 0 | 0 |
| | Availability | 100 | 0 | 0 |
| | Fundamentals of Computer Architecture | 33.3 | 66.7 | 0 |
| | Memory System Hierarchy | 25 | 75 | 0 |
| | Communication and Interfacing | 0 | 100 | 0 |
| | Processor System Design | 60 | 40 | 0 |
| SPIM | Usability | 100 | 0 | 0 |
| | Availability | 100 | 0 | 0 |
| | Fundamentals of Computer Architecture | 100 | 0 | 0 |
| | Memory System Hierarchy | 100 | 0 | 0 |
| | Communication and Interfacing | 75 | 6.3 | 18.7 |
| | Processor System Design | 100 | 0 | 0 |

Figure 1.

The survey indicates that the usability and availability was high for the simulators under examination. Different simulators cover different architectures and depending upon the architecture they cover few concepts high as compared to others. As logisim is a specific for simulating digital logic circuits so it has low percentages in Part D as it covers fewer concepts related to the course as compared to the others. The survey indicates overall, faculty members agreed of the above simulators to be fulfilling the criteria to be included into the course.

### B. *Quantitative Analysis*

Qualitative analysis givens an opinion of the faculty members about the simulators usability, availability and the relevance of contents covered in the course. As the questionnaire consists of ordinal data in likert scale and the result was aggregated in percentage upon the members agreed upon and disagreed upon. To check the discrepancies with the parts of the questionnaire measure of center and location technique was used such as mean, median and mode. Due to the nature of the data collect was ordinal median gives the best measure of the *middle.* Due to the range of scale used for the data collection was between -2 to 2 so the mean values came in negative range. Below are the values



| Simulator | Criteria | Mean | Median | Mode |
|---|---|---|---|---|
| ENIAC | Usability | 1.136 | 1 | 1 |
| | Availability | 2 | 2 | 2 |
| | Fundamentals of Computer Architecture | 0.688 | 1 | 2 |
| | Memory System | -0.36 | -1 | -1 |
| | Communication and Interfacing | 0.345 | 1 | 1 |
| | Processor System Design | 0.702 | 1 | 1 |
| VVM | Usability | 1.458 | 1 | 1 |
| | Availability | 1.6 | 2 | 2 |
| | Fundamentals of Computer Architecture | 1.523 | 2 | 2 |
| | Memory System | 0.283 | -0.25 | -0.5 |
| | Communication and Interfacing | 1.19 | 1 | 1 |
| | Processor System Design | 1.078 | 1 | 1 |
| MARS | Usability | 1.332 | 1 | 1 |
| | Availability | 2 | 2 | 2 |
| | Fundamentals of Computer Architecture | 1.398 | 1 | 1 |
| | Memory System | 0.923 | 1 | 1 |
| | Communication and Interfacing | 1.345 | 1 | 1 |
| | Processor System Design | 1.178 | 1 | 1 |
| Logisim | Usability | 1.555 | 2 | 1.5 |
| | Availability | 2 | 2 | 2 |
| | Fundamentals of Computer Architecture | 0 | -1 | -1 |
| | Memory System | -0.25 | -1 | -1 |
| | Communication and Interfacing | -1 | -1 | -1 |
| | Processor System Design | 0.8 | 2 | 2 |
| SPIM | Usability | 1.42 | 1.25 | 1 |
| | Availability | 2 | 2 | 2 |
| | Fundamentals of Computer Architecture | 1.833 | 2 | 2 |
| | Memory System | 1.5 | 1.5 | 2 |
| | Communication and Interfacing | 1.283 | 1.5 | 2 |
| | Processor System Design | 1.15 | 1 | 1 |

Figure 2.

The values of corresponds correctly to the percentage of the qualitative analysis. It was seen that the aggregate percentage of strongly disagree/ disagree increases made the effect of the quantitative values towards negative. The value of median in decimal was calculated as there are two median values so adding the both values and divided by two. Rest of the percentage of the qualitative analysis correspond the values of median for the quantitative analysis.

## VII. Conclusion & Future Work

Use of simulators in studying Computer Architecture and Organization help the students in understanding the concepts delivered in the classroom. The strategy adapted in the study discussed the usability, availability and the course contents covered by different simulators before inducting them into the laboratory work. Survey was conducted between faculty members and evaluated using qualitative and quantitative analysis.

The evaluation, based on the criteria laid by the faculty members and also the input from the department chairman, as no simulator covers all topics so combination of simulators were surveyed depending upon different architecture and the topics covered in class room. The overall result was satisfactory and it was decided to include all of the simulators in the laboratory work.

In future, survey on simulators would be conducted and see what are the difficulties faced by the students and what students benefited from use of simulators.

Later evaluation will be conducted on the knowledge grasped by students from the use of simulators by comparing the past results of students when there was no laboratory work conducted in comparision to the current result of the students and will see if there is any significant difference in the behavior of the students learning process.

## Acknowledgment

The authors acknowledge the encouragement, support and guidance given by Chairman Computer Engineering Department **Dr. Syed Misbahuddin** to prepare Lectures, Laboratory manual and selecting simulators.

Special thanks to all other faculty members for helping during the research and giving their valuable suggestion and guidance.

# Backstepping based adaptive sliding mode control for spacecraft attitude maneuvers

Binglong Cong, Xiangdong Liu and Zhen Chen
Key laboratory for Intelligent Control & Decision of Complex Systems, School of Automation
Beijing Institute of Technology, Beijing, China 100081
Email: {cbl, xdliu, chenzhen76}@bit.edu.cn

***Abstract*—This paper aims to address the robust control problem of rigid spacecraft attitude maneuvers in the presence of inertia matrix uncertainty and external disturbance. A backstepping based adaptive sliding mode control (B-ASMC) design is proposed as a solution, where the upper bounds of the parametric uncertainty and disturbance are not required in advance. Compared to current adaptive sliding mode control (ASMC) design, the B-ASMC design has two advantages. Theoretically, the asymptotical stability of the attitude states rather than the sliding function is guaranteed. Practically, the over-adaptation problem in current ASMC design is alleviated and the system performance is improved. Detailed design principle and rigorous closed-loop system stability analysis are provided. A large angle attitude maneuver is employed in the numerical simulation to verify the effectiveness of the proposed algorithm.**

***Index Terms*—attitude maneuver, adaptive sliding mode control, backstepping, over-adaptation.**

## I. Introduction

With the development of aerospace technologies, more and more space missions require that the involved spacecraft implements attitude maneuvers with large angles. Design of an attitude control system for such case poses a challenging problem, including the nonlinear characteristics in the attitude dynamics & kinematics, modeling uncertainty and unexpected external disturbances. Thus, in order to guarantee the control performance, it is necessary to employ nonlinear robust control methods. Sliding mode control (SMC) is a powerful nonlinear control method that is well known for its strong robustness. SMC can provide many good properties, such as insensitivity to model uncertainty, disturbance rejection, and fast dynamic response, which make it a welcome approach for spacecraft attitude control [1]–[4].

According to the equivalent control concept, current SMC algorithms generally consist of two parts, the continuous equivalent control component and the discontinuous switching control component. In order to satisfy the reaching condition, the switching gain should be larger than the upper bounds of the model uncertainty and disturbance. However, those bounds are hard to find in many practical situations. Therefore, conservative design is generally adopted, where the switching gain is selected sufficiently large, such as those in [1]–[4]. Nonetheless, a large switching control component may aggravate the chattering problem which could excite the unmodelled dynamics and may lead to instability.

To eliminate the need of uncertainty and disturbance bounds, adaptive scheme is integrated into SMC design, which is known as the ASMC technique. At the initial stage, it is assumed that the lumped uncertainty was bounded by a linear function of the state-norm. Correspondingly, adaptive laws were designed for the linear function coefficients, as suggested in [5]–[7]. In particular, in [7], an ASMC algorithm was proposed for the attitude stabilization of a rigid spacecraft, where the lumped uncertainty is assumed to be bounded by a linear function of the norms of angular velocity and quaternion. Subsequently, the lumped uncertainty was assumed to be bounded by an unknown constant and consequently a simple adaptive law was proposed for the switching gain calculation in [8]. Subsequent results can be found in many applications such as internal combustion engines [9], induction servomotor [10], planetary gear-type inverted-pendulum [11], etc. However, on the basis of Barbalat lemma, all the ASMC algorithms mentioned above can only guarantee that the sliding function is asymptotically stable but not the system states. And the system performance has not been taken into account.

On the other hand, the backstepping design technique has been widely used to control nonlinear systems with matched or unmatched uncertainties in recent years (see [12] and references therein). The key feature of backstepping design is that it stabilizes the system states through a step-by-step recursive process. Once the final step is completed, the stability of the entire system is guaranteed naturally. However, conventional backstepping design mainly assume that the lumped uncertainty is constant or slowly changing. When the derivative of the lumped uncertainty cannot be regarded as zero, backstepping design with integral adaptive laws are no longer applicable. Recently, there has been continuous efforts to combine the backstepping technique with the SMC method, such as [13]–[15]. Unfortunately, a prior knowledge of the lumped uncertainty bound is required.

Considering the characteristics of both the ASMC method and the backstepping technique, it is natural to combine those two design methodologies to preserve their advantages and at the same time overcome their drawbacks mentioned above, which leads to the proposed B-ASMC design. In this paper, we focus on the robust attitude control for a rigid spacecraft, where the inertia matrix uncertainty and external disturbance are considered. Noticing the cascade structure of the attitude control system, the attitude controller is designed in the backstepping framework, where the ASMC algorithm is

978-1-4673-1560-9/12/$31.00 ©2012 IEEE

designed in the final step to deal with the lumped uncertainty. By virtue of the backstepping design procedure, the proposed B-ASMC algorithm can guarantee the asymptotical stability of the closed-loop system not just the sliding function. Moreover, the system performance can be improved by the proposed algorithm.

## II. Preliminaries

### A. Mathematical Model

Consider a thruster control rigid spacecraft, whose attitude dynamics is governed by the following equation:

$$J\dot{\omega}_b + S(\omega_b)J\omega_b = T_b + T_d \tag{1}$$

where $J \in \mathbb{R}^{3\times 3}$ is the spacecraft inertia matrix, $\omega_b \in \mathbb{R}^3$ denotes the angular velocity vector of $\mathcal{F}_B$, the body-fixed frame, with respect to $\mathcal{F}_I$, the inertia frame. $S(\cdot)$ is the skew-symmetric matrix operator, which is operated as follows:

$$S(\alpha)\beta = \alpha \times \beta$$

where $\alpha$ and $\beta$ are the vectors in $\mathbb{R}^3$. $T_b \in \mathbb{R}^3$ is the vector of control torque provided by the thrusters, $T_d \in \mathbb{R}^3$ is the time-varying external disturbance vector, including environmental and non-environmental disturbance torques. Furthermore, the inertia matrix uncertainty is considered. Let $J = \hat{J} + \Delta J$ with $\Delta J$ the uncertainty caused by the change in mass properties and $\hat{J} = \mathrm{diag}(J_1, J_2, J_3)$ the nominal inertia matrix. Then (1) is described as:

$$\hat{J}\dot{\omega}_b + S(\omega_b)\hat{J}\omega_b = T_b + T_d - \Delta J\dot{\omega}_b - S(\omega_b)\Delta J\omega_b \tag{2}$$

According to the structural feature in (2), one can merge all the elements caused by inertia matrix uncertainty and external disturbance as the lumped uncertainty, i.e., let $d = T_d - \Delta J\dot{\omega}_b - S(\omega_b)\Delta J\omega_b$. Correspondingly, the attitude dynamics is rewritten as:

$$\hat{J}\dot{\omega}_b + S(\omega_b)\hat{J}\omega_b = T_b + d \tag{3}$$

From (3), it is clear that the lumped uncertainty is matched to the system. Without loss of generality, it is assumed that $d$ is smooth and satisfies $\|d\|_\infty < d_{\max}$ with $d_{\max}$ the unknown upper bound and $\|\cdot\|_\infty$ the vector infinity-norm.

As for the attitude representation, quaternion and modified Rodrigues parameters (MRPs) are the two most popular parameters. Quaternion is characterized by its global non-singularity. However, the use of quaternion requires an extra parameter, which leads to a non-minimal parameterization [4]. For the attitude maneuver whose principal angle is within $(-2\pi, 2\pi)$, MRPs can provide a nonsingular minimal attitude description. Moreover, by introducing the shadow MRPs and a switching mechanism, MRPs turn out to be a nonsingular, bounded, minimal attitude representation. Therefore, MRPs are utilized in this paper, whose kinematics is:

$$\dot{\sigma}_b = M(\sigma_b)\omega_b \tag{4}$$

where $\sigma_b \in \mathbb{R}^3$ denotes the inertial MRPs vector of $\mathcal{F}_B$ with respect to $\mathcal{F}_I$. $M(\sigma_b)$ is the Jacobian matrix in the form of $M(\sigma_b) = \dfrac{(1-\|\sigma_b\|^2)I_3 + 2S(\sigma_b) + 2\sigma_b\sigma_b^T}{4}$ with $\|\cdot\|$ the vector 2-norm and $I_3$ the $3 \times 3$ identity matrix. Moreover, $M^T(\sigma_b)M(\sigma_b) = m(\sigma_b)I_3$ with $m(\sigma_b) = (1+\|\sigma_b\|^2)^2/16$. The transition matrix from $\mathcal{F}_I$ to $\mathcal{F}_B$ in terms of $\sigma_b$ is:

$$R(\sigma_b) = I_3 + \frac{8S(\sigma_b)S(\sigma_b) - 4(1-\|\sigma_b\|^2)S(\sigma_b)}{(1+\|\sigma_b\|^2)^2} \tag{5}$$

In this paper, the attitude reorientation control problem is considered. Our goal is reorienting the spacecraft from an arbitrary stationary attitude to a desired attitude with zero angular velocity. Denoting the attitude variables of $\mathcal{F}_D$, the desired frame, as $\sigma_d \in \mathbb{R}^3$ and $\omega_d \in \mathbb{R}^3$, the error attitude variables are defined as follows:

$$\sigma_e = \sigma_b \oplus \sigma_d^* \tag{6}$$

$$\omega_e = \omega_b - R(\sigma_e)\omega_d \tag{7}$$

where $\sigma_e \in \mathbb{R}^3$ is the error MRPs, $\oplus$ is the MRPs production operator, characterizing the successive rotations. For two MRPs expressed in their corresponding frames, e.g., $\sigma_1 \in \mathbb{R}^3$ and $\sigma_2 \in \mathbb{R}^3$, it is operated as follows:

$$\sigma_1 \oplus \sigma_2 = \frac{(1-\|\sigma_2\|^2)\sigma_1 + (1-\|\sigma_1\|^2)\sigma_2 - 2S(\sigma_1)\sigma_2}{1 + \|\sigma_2\|^2\|\sigma_1\|^2 - 2\sigma_2^T\sigma_1}$$

$\sigma_d^*$ is the inverse of $\sigma_d$, which is extracted from $R^{-1}(\sigma_d)$ and $\sigma_d^* = -\sigma_d$, $R(\sigma_e)$ and $R(\sigma_d)$ are the transition matrices from $\mathcal{F}_D$ to $\mathcal{F}_B$ and from $\mathcal{F}_I$ to $\mathcal{F}_D$, and their expressions in terms of $\sigma_e$ and $\sigma_d$ can be obtained by replacing $\sigma_b$ by $\sigma_e$ and $\sigma_d$ in (5). As $\omega_d = 0$, one has $\omega_e = \omega_b$. Therefore, the error attitude dynamics is expressed same as (3). As mentioned in [17], if the attitude variables pairs $(\sigma_b, \omega_b)$ and $(\sigma_d, \omega_d)$ satisfy the MRPs kinematics formulation described in (4), then the error attitude variables pair $(\sigma_e, \omega_e)$ also satisfies the MRPs kinematics formulation. Then, the attitude control system is governed by the following equations:

$$\begin{cases} \hat{J}\dot{\omega}_b + S(\omega_b)\hat{J}\omega_b = T_b + d \\ \dot{\sigma}_e = M(\sigma_e)\omega_b \end{cases} \tag{8}$$

### B. Problem Statement

The control objective can be summarized as follows: design a robust control algorithm to steer the attitude variables pair $(\sigma_b, \omega_b)$ from $(\sigma_b(0), 0)$ to $(\sigma_d, 0)$ (or equivalently render $\lim\limits_{t\to\infty} \sigma_e = \lim\limits_{t\to\infty} \omega_b = 0$) when the lumped uncertainty upper bound $d_{\max}$ is unknown in advance.

## III. Main Results

### A. Conventional ASMC Algorithm Design

In this section, the ASMC algorithm is applied to the attitude control problem under consideration and its major drawback will be revealed. First, define the following nonlinear sliding function $s \in \mathbb{R}^3$:

$$s = \omega_b + \lambda\frac{M^T(\sigma_e)}{m(\sigma_e)}\sigma_e \tag{9}$$

where $\lambda > 0$ is the sliding function gain and $m(\sigma_e)$ can be obtained by replacing $\sigma_b$ in (4) by $\sigma_e$.

According to the design principle presented in [8], following ASMC algorithm can be obtained:

$$T_b = S(\omega_b)\hat{J}\omega_b - \lambda\hat{J}\frac{4M(\sigma_e) - 2\sigma_e\sigma_e^T}{1+\|\sigma_e\|^2}\omega_b - \hat{d}\text{sgn}(s) \quad (10a)$$

with $\hat{d}$ the estimation of $d_{\max}$ which is given by

$$\hat{d} = c\int_0^t \|s\|_1 d\tau \quad (10b)$$

where $c > 0$ is the adaptive gain, $\text{sgn}(\cdot)$ is the sign function and $\|s\|_1 = s^T\text{sgn}(s)$ denotes the vector 1-norm of $s$.

By selecting the Lyapunov candidate function in the form of

$$V = \frac{1}{2}s^T\hat{J}s + \frac{1}{2c}\tilde{d}^2$$

where $\tilde{d} = \hat{d} - d_{\max}$ denotes the estimation error, it is easy to obtain that the time derivative of the above Lyapunov function is

$$\begin{aligned}\dot{V} &= s^T d - d_{\max}s^T\text{sgn}(s)\\ &\le -\eta\|s\|_1\end{aligned} \quad (11)$$

where $\eta = d_{\max} - \|d\|_\infty$. On the basis of the Barbalat lemma, one can conclude that $\lim\limits_{t\to\infty} s = 0$.

There are two major problems of the above ASMC algorithm. Theoretically speaking, $\lim\limits_{t\to\infty} s = 0$ cannot rigorously guarantee $\lim\limits_{t\to\infty}\omega_b = \lim\limits_{t\to\infty}\sigma_e = 0$, i.e., the asymptotic stability of the closed-loop system is not actually achieved. Practically speaking, the ASMC algorithm does not consider the dynamics of the reaching phase, which may arise an over-adaptation of the switching gain with respect to the lumped uncertainty bound and lead to an undesirable system performance. In the following, we try to address those problems by combining the ASMC technique with the backstepping design and present the B-ASMC algorithm.

### B. B-ASMC Algorithm Design

As demonstrated in [18], an important property of the system in (8) is that it describes the attitude control system in a *cascade interconnection*, which accords with the strict feedback form in backstepping design. With this in mind, it is possible to design the ASMC algorithm in the backstepping framework and use its key feature to guarantee the stability of the closed-loop system.

First, in the attitude kinematics subsystem, treat the angular velocity as an independent input, then there exists a state feedback stabilizing control law $\omega_b^*(\sigma_e)$ in the form of

$$\omega_b^*(\sigma_e) = -k_\sigma\frac{M^T(\sigma_e)}{m(\sigma_e)}\sigma_e = -k_\sigma\frac{4}{1+\|\sigma_e\|^2}\sigma_e \quad (12)$$

with $k_\sigma > 0$. Now, consider a Lyapunov candidate function for the attitude kinematics subsystem with the form of $V_\sigma = \|\sigma_e\|^2/2 = \sigma_e^T\sigma_e/2$. From (8) and (12), the derivative of the above Lyapunov candidate is

$$\dot{V}_\sigma = -k_\sigma\sigma_e^T\sigma_e \le 0 \quad (13)$$

If the angular velocity $\omega_b$ is identical to $\omega_b^*(\sigma_e)$, the attitude kinematics subsystem response is characterized by

$$\sigma_e = \exp(-k_\sigma(t-t_i))\sigma_e(t_i) \quad (14)$$

with $t_i$ the time when $\omega_b = \omega_b^*(\sigma_e)$, which implies a good error MRPs response would be achieved.

Then, in order to guarantee $\omega_b$ can track $\omega_b^*(\sigma_e)$, a coordinated transformation is utilized. Let $z = \omega_b - \omega_b^*(\sigma_e) \in \mathbb{R}^3$, the attitude control system described by $\sigma_e$ and $z$ is represented as:

$$\begin{cases}\hat{J}\dot{z} = T_b - S\left(\omega_b^*(\sigma_e)+z\right)\hat{J}\left(\omega_b^*(\sigma_e)+z\right) + d - \hat{J}\dot{\omega}_b^*(\sigma_e)\\ \dot{\sigma}_e = M(\sigma_e)z + M(\sigma_e)\omega_b^*(\sigma_e)\end{cases} \quad (15)$$

where $\dot{\omega}_b^*(\sigma_e)$ can be analytically expressed as

$$\dot{\omega}_b^*(\sigma_e) = -k_\sigma\frac{4M(\sigma_e) - 2\sigma_e\sigma_e^T}{1+\|\sigma_e\|^2}\left(\omega_b^*(\sigma_e)+z\right)$$

Here, using the ASMC methodology, the attitude control law for the attitude dynamics subsystem is designed as:

$$\begin{aligned}T_b =& S\left(\omega_b^*(\sigma_e)+z\right)\hat{J}\left(\omega_b^*(\sigma_e)+z\right) + \hat{J}\dot{\omega}_b^*(\sigma_e)\\ &- k_\omega\hat{J}z - \hat{d}\text{sgn}(z)\end{aligned} \quad (16a)$$

with

$$\hat{d} = c\int_0^t \|z\|_1 d\tau \quad (16b)$$

Consider a Lyapunov candidate function for the attitude dynamics subsystem in the form of

$$V_\omega = \frac{1}{2}z^T\hat{J}z + \frac{1}{2c}\tilde{d}^2 \quad (17)$$

According to (16a) and (16b), the derivative of the above Lyapunov function is

$$\begin{aligned}\dot{V}_\omega &= -k_\omega z^T\hat{J}z + z^T\left[d - \hat{d}\text{sgn}(z)\right] + (\hat{d} - d_{\max})z^T\text{sgn}(z)\\ &= -k_\omega z^T\hat{J}z + z^T d - d_{\max}z^T\text{sgn}(z)\\ &\le -k_\omega z^T\hat{J}z - \eta\|z\|_1 \le -k_\omega z^T\hat{J}z\end{aligned}$$

In order to obtain the control law for the entire system, we should explore the interconnection between the virtual control law in (12) and the attitude control law in (16a) and (16b). Thus, the B-ASMC algorithm is presented as:

$$\begin{aligned}T_b =& S\left(\omega_b^*(\sigma_e)+z\right)\hat{J}\left(\omega_b^*(\sigma_e)+z\right) + \hat{J}\dot{\omega}_b^*(\sigma_e)\\ &- M^T(\sigma_e)\sigma_e - k_\omega\hat{J}z - \hat{d}\text{sgn}(z)\end{aligned} \quad (18a)$$

with

$$\hat{d} = c\int_0^t \|z\|_1 d\tau \quad (18b)$$

Now, we are ready to state the following theorem:

*Theorem 1:* For the attitude control system described in (8), the B-ASMC algorithm in (18a) and (18b) can globally asymptotically stabilize the closed-loop system in the presence that the lumped uncertainty upper bound $d_{\max}$ is unknown in advance.

*Proof 1:* Chose the Lyapunov function for the entire system as

$$V = V_\sigma + V_\omega \tag{19}$$

By taking the time derivative along the system trajectory, one has:

$$\begin{aligned}\dot{V} =& \sigma_e^T M(\sigma_e) z + \sigma_e^T M(\sigma_e)\omega_b^*(\sigma_e) \\ & - k_\omega z^T \hat{J} z - z^T M^T(\sigma_e)\sigma_e + z^T\left[d - d_{\max}\mathrm{sgn}(z)\right] \\ =& - k_\sigma \sigma_e^T \sigma_e - k_\omega z^T \hat{J} z + z^T d - d_{\max} z^T \mathrm{sgn}(z) \\ \leq& - k_\sigma \sigma_e^T \sigma_e - k_\omega z^T \hat{J} z - \eta \|z\|_1 \\ \leq& - k_\sigma \sigma_e^T \sigma_e - k_\omega z^T \hat{J} z\end{aligned}$$

where we have used the fact that $\sigma_e^T M(\sigma_e) z = z^T M^T(\sigma_e)\sigma_e$ and $\|d\|_\infty < d_{\max}$.

Let $\chi = k_\sigma \sigma_e^T \sigma_e + k_\omega z^T \hat{J} z$. It is obvious that $\chi$ is uniformly continuous. By integrating the above equation from zero to $t$, one has:

$$\int_0^t \dot{V} d\tau \leq -\int_0^t \chi d\tau \Rightarrow V(0) \geq \int_0^t \chi d\tau \tag{20}$$

Taking the limits as $t \to \infty$ on both sides of (20) gives

$$\infty > V(0) \geq \lim_{t\to\infty} \int_0^t \chi d\tau \tag{21}$$

On the basis of Barbalat lemma, we can obtain $\lim_{t\to\infty} \chi = 0$, which implies that $\lim_{t\to\infty} \sigma_e = \lim_{t\to\infty} z = 0$. As $\lim_{t\to\infty} \sigma_e = 0$, one has $\lim_{t\to\infty} \omega_b^*(\sigma_e) = 0$. According to the definition of $z$, it is easy to obtain that $\lim_{t\to\infty} \omega_b = 0$. As $V$ is radially unbounded, then we can obtain the conclusion.

### C. Discussions

Here are some remarks:

*Remark 1:* By comparing the ASMC algorithm with the B-ASMC algorithm, one can find that the transformed variable $z$ is actually the sliding function $s$. Therefore, if we rewrite the B-ASMC algorithm in terms of $\sigma_e$ and $s$, there are two additional terms of the B-ASMC algorithm as compared to the ASMC algorithm, $-k_\omega \hat{J} s$ and $-M^T(\sigma_e)\sigma_e$.

The first term is used to improve the system performance by specifying dynamics in the reaching phase. Such a strategy belongs to the so called the *reaching law* method, which was presented in [19]. The *reaching law* is a differential equation which specifies the dynamics of the sliding function. When it is used in the ASMC design, additional benefit can be shown, which has not been fully explored in the literature. For this case, the sliding function dynamics is governed by $\hat{J}\dot{s} = -k_\omega \hat{J} s - \hat{d}\mathrm{sgn}(s)$. As the initial value of $\hat{d}$ is zero, before the adaptation scheme can produce a large enough $\hat{d}$ to satisfy the reaching condition, the term $-k_\omega \hat{J} s$ provides a necessary damping to speed up the reaching phase. On the other hand, it is well known that the basic idea of the ASMC method lies in that the switching gain can be adjusted by the departure from the sliding surface. However, from the adaptive law in (10b), one can see that the integral action starts from the very beginning and any departure from the sliding surface will results in an increase of the switching gain $\hat{d}$. Therefore, if the initial system error is large, or equivalently the initial system trajectory is located far from the sliding surface, the resulting $\hat{d}$ generated by the ASMC algorithm is much larger than the necessary value. Due to the fact that the chattering level is directly determined by the switching gain, the chattering phenomenon is serious in current ASMC design. However, by virtue of $-k_\omega \hat{J} s$, such an over adaptation problem would be weakened due to the fact that part of role of impelling the system trajectory to the sliding surface has been transferred from the $-\hat{d}\mathrm{sgn}(s)$ term to the $-k_\omega \hat{J} s$ term. The parameter $k_\omega$ serves as a tuning parameter dealing with the trade-off between the chattering level and control torque amplitude.

The second term, $-M^T(\sigma_e)\sigma_e$, is used to guarantee the asymptotical stability of the closed-loop system, which has already been verified in the above proof.

*Remark 2:* In [20], the sliding motion with an infinite frequency of the control switching is defined as the *ideal sliding*. In *ideal sliding*, the system trajectory is strictly constrained on the sliding surface. Whereas, due to the switching imperfection, i.e., the switching frequency is finite, sliding motion only takes place in a small neighborhood of the sliding surface, which is defined as the *real sliding*. Recalling the adaptive law in (18b), the switching gain will converge to a bounded value only in *ideal sliding*. However, in *real sliding*, as the sliding function is not identically equal to zero, $\hat{d}$ will become unbounded. For implementation in practice, the adaptive law has to be modified to get a bounded switching gain, such as the so-called $\sigma$-modification in [6]. In this paper, the approach proposed in [20] will be used, where the adaptive law in (18b) is modified as:

$$\hat{d} = \begin{cases} c\int_0^t \|s\|_1 \mathrm{sgn}(\|s\|_1 - \epsilon) d\tau & \text{if} \quad \hat{d} > \mu \\ \int_0^t \mu d\tau & \text{if} \quad \hat{d} \leq \mu \end{cases} \tag{22}$$

where $\mu > 0$ is a very small scalar to ensure $\hat{d}$ is positive and $\epsilon > 0$ is carefully chosen to deal with the trade-off in control accuracy and bounded switching gain. Further details on $\epsilon$ tuning can refer to [20].

## IV. Numerical Simulation

In this section, a large angle attitude maneuver is employed to verify the effectiveness of the proposed B-ASMC algorithm by comparing it with the ASMC algorithm.

The spacecraft inertia matrix for the controller design is $\hat{J} = \mathrm{diag}(48, 25, 61.8)$ (kg.m) and the uncertainty is 10% of the nominal value. $T_d = [\sin(0.2t), 2\cos(0.3t), 3\sin(0.4t)]^T \times 10^{-1}$ (N.m) is the external disturbance. The initial attitude variables of the spacecraft are $\sigma_b(0) = [-0.2, 0.3, 0.1]^T$ and $\omega_b(0) = [0, 0, 0]^T$ (rad/s). The desired attitude is $\sigma_d = [0.1, 0.2, -0.3]^T$ with the desired angular velocity $\omega_d = [0, 0, 0]^T$ (rad/s). The B-ASMC parameters are $k_\sigma = 0.2$, $k_\omega = 0.6$ and the adaptive gain is selected as $c = 1$. For comparison, the ASMC parameter is $\lambda = 0.2 = k_\sigma$ and the adaptive gain is also selected as $c = 1$. The simulation results are shown in Fig.1–Fig.5, where the superscripts $x, y, z$ denote the triaxial components of related vectors.

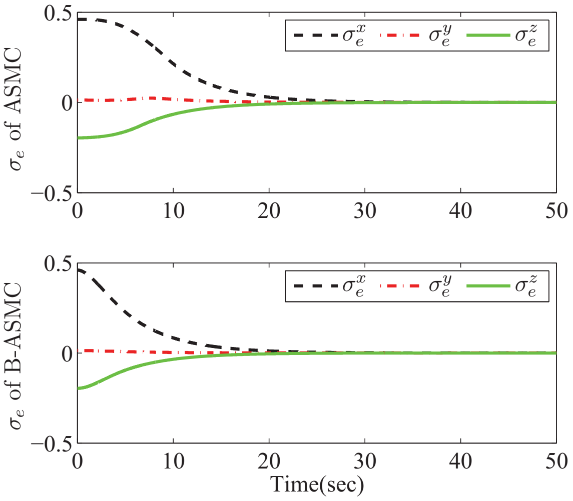

Fig. 1. Error MRPs response comparison

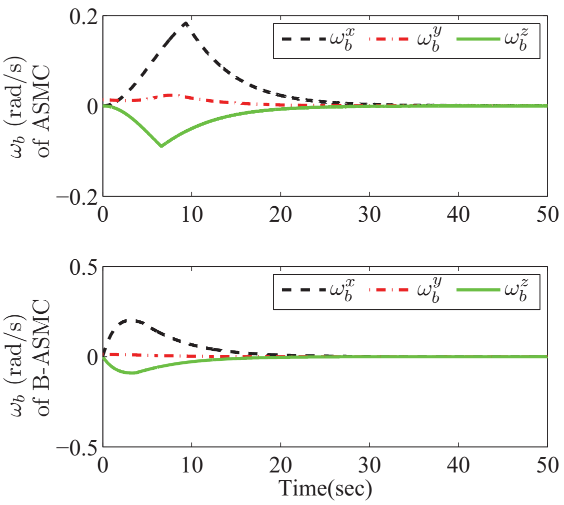

Fig. 2. Angular velocity response comparison

Fig.1 and Fig.2 illustrate the evolutions of the reorientation maneuver controlled by the ASMC algorithm and the B-ASMC algorithm in terms of error MRPs and angular velocity, with the corresponding control torque compared in Fig.3. From Fig.1, we can see that the convergence of the error MRPs controlled by the B-ASMC algorithm is faster than the ASMC algorithm. The fact is that the control torque computed by the ASMC algorithm is zero at the initial time according to (10a) and (10b). Therefore, the convergence is very slow at the beginning.

Fig.3 illustrates the control torque comparison, where the chattering problem in the ASMC algorithm is more serious

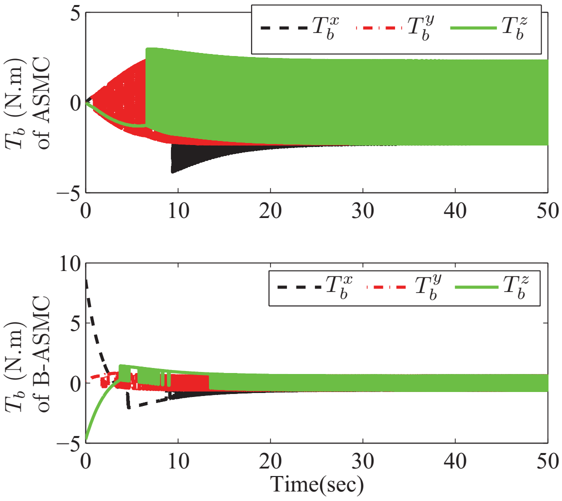

Fig. 3. Control torque response comparison

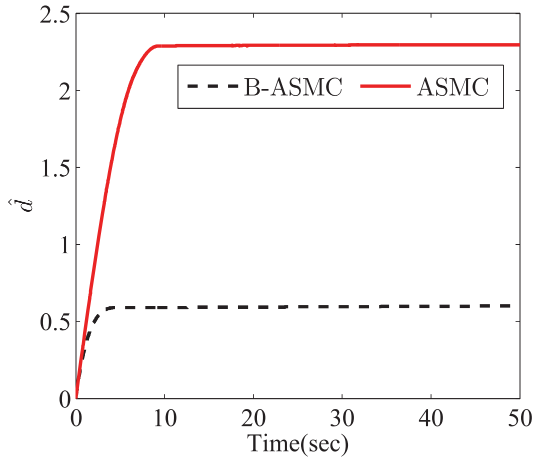

Fig. 4. $\hat{d}$ comparison between two algorithms

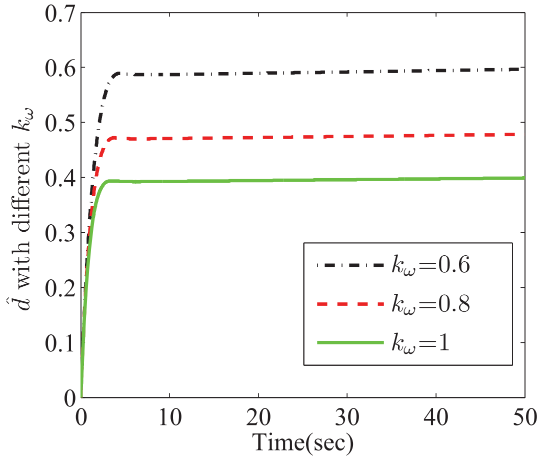

Fig. 5. $\hat{d}$ with different $k_\omega$ in the B-ASMC algorithm

than the B-ASMC algorithm. By examining the switching gains generated by the two control algorithms, as shown in Fig.4, it is clear that the resulting $\hat{d}$ updated by the B-ASMC algorithm is much smaller than the ASMC algorithm, which verifies that the B-ASMC algorithm can weaken the over adaptation problem in the ASMC algorithm and the chattering phenomena is correspondingly reduced. Moreover, $\hat{d}$ generated by the B-ASMC algorithm with different $k_\omega$ is illustrated in Fig.5, from which we can see that the larger the $k_\omega$ is, the smaller the $\hat{d}$ will be and consequently the lower chattering phenomena. However, it should be pointed out that large $k_\omega$ will result in a large initial control torque, as shown in Fig.3.

## V. Conclusion

This paper presents a B-ASMC design for the spacecraft attitude control problem. The proposed algorithm solves the theoretical inadequacy in current ASMC design, where the asymptotical stabilities of the sliding function and the entire closed-loop system are achieved. The system performance is improved by virtue of two additional terms in the control law as compared to current ASMC algorithms. Moreover, the over adaptation problem in ASMC design is also considered and a lower-chattering control signal is achieved. The issue of large initial control torque requirement in B-ASMC will be a topic of in the future work.

# Necessary and Sufficient Conditions for Consensus of Multi-Agent Systems with Nonlinear Dynamics and Variable Topology

Lijing Dong, Senchun Chai, Baihai Zhang
School of Automation
Beijing Institute of Technology
Beijing, China
yangyang304@bit.edu.cn

*Abstract*—**This paper studies some necessary and sufficient conditions for consensus of continuous multi-agent systems with nonlinear node dynamics and variable topology. The multi-agent systems are under variable topology. Basic theoretical analysis is carried out for the case where for each agent the nonlinear dynamics are governed by the position terms of the neighbor nodes. A necessary and sufficient condition associated with eigenvalues is given to ensure consensus of the nonlinear multi-agent system. Based on this result, a simulation example is given to verify the theoretical analysis.**

***Keywords- Nonlinear Multi-agent system; Consensus; Variable Topology***

## I. Introduction

Since consensus of multi-agent systems (MAS) is a fundamental problem in the MAS research area, it has attracted increasing attention of researchers from various disciplines of engineering, biology and science. In networks of agents, consensus means to reach an agreement regarding a certain quantity of interest that depends on the state of all agents. A consensus algorithm is an interaction rule that specifies the information exchange between an agent and all of its neighbors on the network. Such problems have been formulated as consensus of leaderless problems or leader-following problems [1-3]. For a cooperative multi-agent system, leaderless consensus means that each agent updates its state based on local information of its neighbors such that all agents eventually reach an agreement on a common value, while leader-following consensus means that there exists a virtual leader which specifies an objective for all agents to follow.

In the past few years, the multi-agent systems with integer dynamics [4-6] or invariant topology [1, 4, 5] have been widely studied by many researchers due to its simple construction and convenience to analyze. Certainly, there are some researchers spend efforts on multi-agent system with nonlinear dynamics [1, 7] or switching topologies [2, 6, 8], and there have been some outcomes. In [1] a pinning control algorithm was proposed to achieve leader-following consensus in a network of agents with nonlinear second-order dynamics. [7] proposed an adaptive distributed controller with a disturbance estimator to solve the consensus problem under fix topology. By using a common Lyapunov function, [2] extended leader-following consensus control for multi-agent systems, which ensured strong mean square consensus the result, to the switching topology case. In [6], the sampled control protocols are induced from continuous-time linear consensus protocol by using periodic sampling technology and zero-order hold circuit. Nevertheless, since consensus problem of multi-agent associated with both nonlinear dynamics and variable topology is extremely difficult and complicated, people rarely discuss it.

However, considering the fact that almost all the physical plants contain nonlinearity and the communication topology may change from time to time for that the velocity of each agent is time-varying and the communication radius is finite, nonlinear dynamics associated with variable topology consensus is of vital necessity. In order to overcome this problem, some knowledge of complex dynamical network is employed. Broadly speaking, the first-order nonlinear consensus problem of multi-agent systems can be treated as a special case of the synchronization problem of complex dynamical networks, which has been extensively studied in the past few decades [9-11]. [9] presents a sufficient and necessary condition of synchronization criteria for a time-varying complex dynamical network, which is cited as Lemma1 in this paper. Based on the author's work in [9], a necessary and sufficient condition associated with eigenvalues, which is briefer and easier to verify, is given to ensure consensus of the nonlinear multi-agent system with variable topology.

The paper is organized as follows. Some preliminaries of graph theory are briefly reviewed in Section 2. Main results are given in Section 3. To illustrate the proposed theoretical results, a numerical simulation is provided in Section 4. And finally, conclusions are drawn in Section 5.

## II. Problem Statement

### A. Notations

This work was supported by National Natural Science Foundation of Youth Science Fund(No. 61104086) the Key Technology Support Program of Scientific Research Base in Beijing Institute of Technology (No.2011CX02010), Excellent Young Scholars Research Fund of Beijing Institute of Technology(No. 2011CX04031) and Research Foundation of Beijing Institute of Technology(No. 20100642007)

978-1-4673-1560-9/12/$31.00 ©2012 IEEE

Some mathematical notations are used throughout this paper. Denote $I_N \in \mathbb{R}^{N\times N}$ as an N-dimensional identity matrix, $1_N = [1,1,\cdots,1]^T \in \mathbb{R}^N$ as a vector of all ones. Let $A^T$ and $A^{-1}$ be the transpose and the inverse of matrix $A$ , respectively. $\lambda_{\max}(A)$ denotes the maximal eigenvalue of matrix $A$ . $\|\bullet\|$ denotes Euclidean norm.

### *B. Preliminaries in graph theory*

A directed graph, denoted by $G=\{v,\varepsilon,A\}$ be a weighted digraph with a node set $v=\{1,2,\ldots,N\}$ , an edge set $\varepsilon \subseteq v\times v$ and a weighted adjacency matrix $A=(a_{ij})_{N\times N}$ with nonnegative elements [12].We consider that $(i,j)\in\varepsilon$ if and only if vertex (node) $i$ can send its information to vertex $j$ . If $(i,i)$Î $e$ , we say that vertex $i$ has self-loop. In this paper, it is assumed that no self-loop exists. The set of neighbors of vertex $i$ is denoted by $N_i = \{j|\, j$ Î $v, (j,i)$ Î $e\}$, where $j \notin N_i$, which means there is no information flow from vertex $j$ to vertex $i$ , then $a_{ij}=0$ , otherwise $a_{ij}>0$ . The in-degree and out-degree of node $i$ are, respectively, defined as [13].

$$\deg_{in}(i) = \sum_{j=1,j\neq i}^{N} a_{ij} \quad , \quad \deg_{out}(i) = \sum_{j=1,j\neq i}^{N} a_{ji}$$

A digraph is called balanced if $\deg_{in}(i)=\deg_{out}(i)$, $\forall i \in v$ [12].

Denote $D \triangleq diag\{\deg_{in}(1),\deg_{in}(2),\ldots,\deg_{in}(N)\}$. Then the Laplacian matrix $L$ of the graph $G$ is defined as $L \triangleq D-A$ .

### *C. Equations*

The system to be considered in this paper is a multi-agent system composed of N nonlinear coupled agents, labeled from 1to N, which means $v=\{1,2,\ldots,N\}$ . The multi-agent system with variable topology is assumed to have the following dynamics:

$$\dot{x}_i(t) = f(x_i(t)) + u_i(t), i\in v \tag{1}$$

With control protocol

$$\begin{aligned} u_i(t) = \sum_{j\in \mathrm{N}_i(t)}^{N} & a_{ij}(t)(x_i(t)-x_j(t)) + \\ & b_i(t)(x_i(t)-s(t)), i\in v \end{aligned} \tag{2}$$

where $x_i \in \mathbb{R}$ and $u_i \in \mathbb{R}$ are the state and control input of agent $i$ , respectively, $f(x_i)\in\mathbb{R}$ is a nonlinear continuous function to describe the self-dynamics of agent $i$ . $a_{ij}(t)$ is the $(i,j)$ -th entry of the adjacency matrix $A(t)\in\mathbb{R}^{N\times N}$ at time $t$ , where $s\in\mathbb{R}$ is the state of the virtual leader for multi-agent system (1), which is an isolated agent described by $\dot{s}(t)=f(s(t))$ . $b_i(t)$ indicates the accessibility of $s(t)$ by agent $i$ at time $t$ . $b_i(t)>0$ indicates the case that $s(t)$ is accessible by agent $i$ , and $b_i(t)=0$ indicates the case that $s(t)$ is not accessible by agent $i$ .

Let

$$B(t) = diag\{b_1(t), b_2(t), \cdots, b_N(t)\}$$
$$b(t) = col\{b_1(t), b_2(t), \cdots, b_N(t)\}.$$

***Definition 1:*** The multi-agent system (1) is said to achieve synchronization if $\lim_{t\to\infty}\|x_i(t)-s(t)\|=0, i\in \upsilon$ for any initial condition.

Denote $\bar{G}=\{\bar{v},\bar{\varepsilon},\bar{A}\}$ as the graph considering $s(t)$ into $G$ . Denote $\bar{L}(t)=L(t)+B(t)$ as the Laplacian matrices of $\bar{G}$ at time $t$ .

## III. MAIN RESULTS

This section presents necessary and sufficient conditions for nonlinear multi-agent system with variable topology.

Define

$$x(t) = col\{x_1(t), x_2(t), \cdots, x_N(t)\}$$

$$S(t) = col\{s(t), s(t), \cdots, s(t)\}$$

With the fact that $L1_N=0$ and $B1_N=b$, we can rewrite the multi-agent system (1) as

$$\begin{aligned} \dot{x}(t) &= f(x(t)) + (L(t)+B(t))x(t) - B(t)1_N s(t) \\ &= f(x(t)) + (L(t)+B(t))(x(t)-S(t)) \end{aligned} \tag{3}$$

Define

$\xi(t) = col\{\xi_1(t), \xi_2(t), \cdots, \xi_N(t)\}$ with $\xi_i(t) = x_i(t) - s(t)$ .

Then the error closed-loop system can be deduced,

$$\dot{\xi}(t) = f(\xi(t)+s(t)) - f(s(t)) + (L(t)+B(t))\xi(t) \tag{4}$$

***Lemma1****[9]:* Suppose that $Df(s(t))$ , which is the Jacobian of $f$ evaluated at $s(t)$ , is bounded. There exists a real matrix $\phi(t)$ , nonsingular for all $t$ , such that $\phi^{-1}(t)(L(t)+B(t))^T\phi(t) = diag\{\lambda_1(t),\lambda_2(t),\cdots,\lambda_N(t)\}$ and $\dot{\phi}^{-1}(t)\phi(t) = diag\{\beta_1(t),\beta_2(t),\cdots,\beta_N(t)\}$ . The control protocol (2) solves the consensus problem of nonlinear multi-agent system with variable topology is stable if and only if the linear time-varying systems

$$\begin{aligned}&\dot{w}_k(t) = \left[Df(s(t)) + \lambda_k(t) - \beta_k(t)\right] w_k(t)\\ &k = 1,2,\cdots,N\end{aligned} \tag{5}$$

are stable.

For linear continuous time-varying system given by

$$\dot{y}(t) = A(t)y(t), y(t_0) = y_0 \tag{6}$$

with $y(t) \in \mathbb{R}^n$, it is assumed that $A(t)$ is continuous in $t$. The following classical notation of stability, known as stability in sense of Lyapunov is recalled.

***Definition 2:*** Let $t_0$ be any real number. If for all $\delta > 0$, there exists $r(t_0,\delta) > 0$ such that $\left\|y(t_0)\right\| < r(t_0,\delta)$ implies $\left\|y(t)\right\| < \delta$ for all $t \ge t_0$, then the system (6) is stable in the sense of Lyapunov.

Define

$$w(t) = col\{w_1(t), w_2(t), \cdots, w_N(t)\}$$

System (5) can be rewritten as

$$\dot{w}(t) = \Lambda(t)w(t), w(t_0) = w_0 \tag{7}$$

with

$$\begin{aligned}\Lambda(t) = diag\{&Df(s(t)) + \lambda_1(t) - \beta_1(t), Df(s(t)) + \lambda_2(t) - \beta_2(t)\\ &,\cdots, Df(s(t)) + \lambda_N(t) - \beta_N(t)\}\end{aligned}$$

Consider the following sets

$$\Omega_0 = \left\{w_0 \in \mathbb{R}^n : \left\|w_0\right\|^2 \le \rho_0^2, \rho_0 > 0\right\} \tag{8}$$

and

$$E_t = \left\{w \in \mathbb{R}^n : \left\|w(t)\right\|^2 \le \rho(t)^2, \rho(t) > 0, \forall t \ge t_0\right\} \tag{9}$$

with $\Omega_0 \subseteq E_{t0}$, then the following results can be deduced.

***Theorem 1:*** Consider the linear time-varying system (7) and suppose that $w(t_0) = w_0 \in \Omega_0$ . Then $w(t) \in E_t$ for all $t \ge t_0$ if and only if

$$\rho(t) \ge \hat{\rho}(t) = \rho_0 \lambda_{\max}\left(\Phi(t,t_0)\right) \tag{10}$$

where $\Phi(t,t_0)$ is the state transition matrix of linear time-varying system (7).

***Proof***

*Sufficiency:* Consider the following optimization problem for a given instant of time $t$

$$\begin{cases}\max\limits_{w_0} \rho(t)^2 = w_0^T \Phi(t,t_0)^T \Phi(t,t_0) w_0\\ w_0^T w_0 \le \rho_0^2\end{cases} \tag{11}$$

The Lagrangian of this optimization problem is

$$L(w_0,\gamma) = w_0^T \Phi(t,t_0)^T \Phi(t,t_0) w_0 + \gamma\left(w_0^T w_0 - \rho_0^2\right) \tag{12}$$

with $\gamma \le 0$. The optimal condition $\frac{\partial L}{\partial w_0} = 0$ yields

$$2\Phi(t,t_0)^T \Phi(t,t_0) w_0 + 2\gamma w_0 = 0 \tag{13}$$

Considering the reversibility of state transition matrix $\Phi(t,t_0)$ ,(13) can be rewritten as

$$2\gamma\Phi(t,t_0)^T \left(\Phi(t_0,t)^T \Phi(t_0,t) + \gamma^{-1} I\right)\Phi(t,t_0) w_0 = 0 \tag{14}$$

The optimal condition $\frac{\partial L}{\partial \gamma} = 0$ yields

$$w_0^T w_0 - \rho_0^2 = 0 \tag{15}$$

Multiplying (13) on the left by $w_0^T$ , (16) is obtained,

$$w_0^T \Phi(t,t_0)^T \Phi(t,t_0) w_0 + \gamma w_0^T w_0 = 0 \tag{16}$$

and considering (11) and (15), it yields that

$$\rho(t)^2 = -\rho_0^2 \gamma, \forall t \ge t_0 \tag{17}$$

To obtain a solution $w_0 \ne 0$ satisfying condition (14)and (15), it must have

$$\det\left(\Phi(t_0,t)^T \Phi(t_0,t) + \gamma^{-1} I\right) = 0 \tag{18}$$

which implies that $-\gamma^{-1}$ is an eigenvalue of matrix $\Phi(t_0,t)^T \Phi(t_0,t)$ . Then, from (17) and the reversibility of state transition matrix $\Phi(t,t_0)$ , it follows that

$$\begin{aligned}\hat{\rho}(t)^2 &= \max \rho(t)^2\\ &= \rho_0^2 \lambda_{\max}\left(\Phi(t,t_0)^T \Phi(t,t_0)\right)\end{aligned} \tag{19}$$

In this paper, the state matrix of system (7) , $\Lambda(t)$, is diagonal, then the state transition matrix $\Phi(t,t_0)$ is also diagonal, which results that

$$\lambda_{\max}\left(\Phi(t,t_0)^T \Phi(t,t_0)\right) = \lambda_{\max}^2\left(\Phi(t,t_0)\right)$$

Namely that

$$\hat{\rho}(t) = \lambda_{\max}\left(\Phi(t,t_0)\right) \tag{20}$$

If $\rho(t) \ge \hat{\rho}(t)$ for all $t \ge t_0$ , the state of the system is confined in the family of sets $E_t$ .

*Necessity:* Suppose $w(t) \in E_t$ and that for $t > t_0$ , $\rho(t) < \hat{\rho}(t)$ . This implies that there exist both $w_0 \in \Omega_0$ and

$t > t_0$ such that $w(t)$ does not belong to the ellipsoid $E_t$, which leads to a contradiction. The proof is completed.

For the multi-agent system (1) with nonlinear dynamics and variable topology $\bar{G} = \{\bar{v}, \bar{\varepsilon}, \bar{A}\}$, the necessary and sufficient conditions of the protocol (2) solving the consensus problem will be presented as follows.

***Theorem 2:*** Consider the nonlinear multi-agent system (1) with variable topology $\bar{G} = \{\bar{v}, \bar{\varepsilon}, \bar{A}\}$. Then the control protocol (2) solves the consensus problem if and only if

$$\rho_M = \max_{t \geq t_0} \left\{ \rho_0 \lambda_{\max} \left( \Phi(t, t_0) \right) \right\} < \infty$$

where $\Phi(t, t_0)$ is the state transition matrix of linear time-varying system (7).

***Proof.*** According to Lemma1, it is apparent that we just need to proof the stability of system (7) if we want to proof the stability of system (1).

*Sufficiency:* According to Theorem1, we know that for initial condition $\|w_0\|^2 \leq \rho_0^2$, it yields $\|w(t)\|^2 \leq \rho(t)^2$.

Associated with equation (17) $\rho(t)^2 = -\rho_0^2 \gamma, \forall t \geq t_0$, choose $-\gamma = \left( \dfrac{\delta}{\lambda_{\max}\left( \Phi(t, t_0) \right)} \right)^2$, where $\delta > 0$ is an arbitrary scalar.

Consider the set

$$\left\{ w_0 \in \mathbb{R}^n : \|w_0\|^2 \leq r_0^2 \right\} \qquad (21)$$

with $r_0 = \min\limits_{t \geq t_0} \delta \lambda_{\max}^{-1} \left( \Phi(t, t_0) \right) \leq \dfrac{\delta \rho_0}{\rho_M}$

For all time $t \geq t_0$, (21) presents the set of initial conditions such that $\|w(t)\|^2 \leq \delta^2$.

Then, for all $\delta > 0$, there exists $r = \dfrac{\delta \rho_0}{\rho_M}$ such that $\|w_0\| < r$ which results in $\|w(t)\| < \delta, \quad \forall t \geq t_0$ provided that $\rho_M < \infty$. Then, according to Definition2, the system (7) is stable in sense of Lyapunov. This completes the proof of sufficiency.

*Necessity:* Theorem1 defines in the state space a tube containing all the trajectories of the system (7) under $\forall t \geq t_0$. Then, there exists $t = \hat{t}$ corresponding to the $\hat{\rho}(t)$ such that $\|w(t)\|^2 = \rho_M^2$. If the system (7) is stable, $\rho_M$ must be finite, which yields the fact that *r* is independent of the initial time $\hat{t}_0 \geq t_0$. This completes the proof of necessity.

According to the above, we can obtain that the condition $\rho_M = \max\limits_{t \geq t_0} \left\{ \rho_0 \lambda_{\max} \left( \Phi(t, t_0) \right) \right\} < \infty$ ensures the stability of system (7). From Lemma1, the protocol (2) solves the consensus problem of nonlinear multi-agent system (1) with variable topology if and only if $\rho_M < \infty$. This completes the prove.

## IV. Numerical Example

In this section, a numerical example is given to illustrate the Theorem2 with network (1) under control protocol (2). Consider the nonlinear multi-agent system with variable topology:

$$\dot{x}(t) = -\arctan\left(x(t)\right) + \left(L(t) + B(t)\right)\left(x(t) - s(t) 1_N\right) \quad (22)$$

with $\dot{s}(t) = -\arctan\left(s(t)\right)$, $x(t) = \left[x_1(t), x_2(t), x_3(t)\right]$ and $N = 3$ .Then the Jacobian matrix is $Df\left(s(t)\right) = -\dfrac{1}{1 + s(t)^2}$. Assume that the coupling matrix of system (22) is

$$L(t) + B(t) = \frac{1}{2e^2 - e - 1} \begin{pmatrix} \left(e^2 - 1\right) th(t) + e\arctan(t) & (1 - e) th(t) - 2e\arctan(t) & \left(e - e^2\right) th(t) + e\arctan(t) \\ 2\left(e^2 - 1\right) th(t) + e^2 \arctan(t) & 2(1 - e) th(t) - 2e^2 \arctan(t) & 2\left(e - e^2\right) th(t) + e^2 \arctan(t) \\ 3\left(e^2 - 1\right) th(t) + \arctan(t) & 3(1 - e) th(t) - 2\arctan(t) & 3\left(e - e^2\right) th(t) + \arctan(t) \end{pmatrix}$$

It is easy to verify that there exists a nonlinear real matrix

$$\phi(t) = \frac{1}{2e^2 - e - 1} \begin{pmatrix} 3e^2 - 2 & \left(1 - e^2\right) e^t & -e^{1 + \sin(t)} \\ 1 - 3e & (e - 1) e^t & 2e^{1 + \sin(t)} \\ 2e - e^2 & \left(e^2 - e\right) e^t & -e^{1 + \sin(t)} \end{pmatrix}$$

Such that

$$f^{-1}(t)\left(L(t) + B(t)\right)^T f(t) = diag\,\{0, -\,th(t), -\arctan(t)\}$$

and $\dot{f}^{-1}(t) f(t) = diag\,\{0, -1, -\cos(t)\}$

Thus, system (7) is developed as (23) for instantiation.

$$\dot{w}(t) = \breve{L}(t)\, w(t) \qquad (23)$$

with

$$\breve{L}(t)=diag\left\{-\frac{1}{1+s(t)^{2}},-\frac{1}{1+s(t)^{2}}-th(t)+1,\right.$$
$$\left.-\frac{1}{1+s(t)^{2}}+\cos(t)-\arctan(t)\right\}$$

The state transition matrix is

$$\breve{F}(t)=diag\left\{e^{\int_{t_0}^{t}-\frac{1}{1+s(t)^{2}}dt},e^{\int_{t_0}^{t}\left(\frac{s(t)^{2}}{1+s(t)^{2}}-th(t)\right)dt},e^{\int_{t_0}^{t}\left(-\frac{1}{1+s(t)^{2}}+\cos(t)-\arctan(t)\right)dt}\right\}$$

It is obvious that $\max_{t\geq t_0}\left\{\rho_0\lambda_{\max}\left(\Phi(t,t_0)\right)\right\}<\infty$. Therefore, from Theorem2, we know that the consensus of nonlinear multi-agent system (22) with variable topology and control protocol (2) is achieved.

Fig. 1 describes the errors of three followers with the leader in the multi-agent system under the initial condition $s(0)=1$, $x(0)=[-0.2\ \ 0.5\ \ 2]$.

From Fig. 1, we can see the errors of the three following agents with the leader agent tend to zero as time goes on, which means the multi-agent system (22) reaches an absolute consensus on the state $x$. This verified that the necessary and sufficient conditions can solve the consensus problem of multi-agent system with both nonlinear dynamics and variable topology effectively.

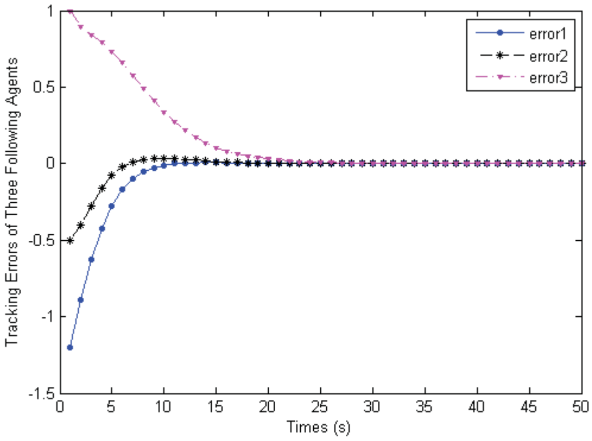

Figure 1. Errors of agents with the leader

## V. Conclusions

A necessary and sufficient condition associated with eigenvalues has been given to ensure consensus of the nonlinear multi-agent system with variable topology. The condition merges the work of [9], which studied controlled synchronization criteria of complex dynamical networks, and some stability theory on linear time-varying system. The necessary and sufficient condition is expressed in a brief way and it is easy to verify.

In the future, second-order consensus problem will be studied based on the work in this paper. Second-order multi-agent system better confirms to the actual situation than the first-order. Therefore, the extension of consensus algorithms from first-order to second-order is non-trivial. The second-order consensus problem is more complicated and challenging.

***Abstract*—This paper deals with the multi-agent consensus problem subject to communication constrains. Two types of communication constrains are discussed in this paper: i) each agent can only exchange quantized data with its neighbors and ii) each agent can only obtain the delayed information from its neighbors. Solutions of the resulting system are defined in the Filippov sense. For the consensus protocol which only considers quantization effect, we prove that Filippov solutions converge to a practical consensus set in a finite time. For the consensus protocol considering quantization and time delay simultaneously, it is shown that Filippov solutions converge to a practical consensus set asymptotically. Moreover, we also present how initial state of the agents, time delay and quantization parameter affect the final practical consensus set. Numerical examples are provided to demonstrate the effectiveness of the obtained theoretical results.**

***Index Terms*—Multi-agent networks, consensus, time delay, quantization.**

## I. Introduction

The concept of consensus originates from the cooperative control, which means all agents reach an agreement on certain quantities of interest. Recently, consensus control has become one of the most focused problems in distributed coordination control of multi-agent networks due to its broad applications in the fields of unmanned aerial vehicles(UAVs), clusters of satellites, automated highway systems and congestion control in communication networks (see, e.g., [1]–[5]).

Due to the physical location, communication bandwidth and unavoidable information losses, only limited information can be sent, transmitted and received by agents in real systems. Hence, consideration of the communication constrains is necessary and important for the design of control strategy or algorithm (see, e.g., [6]–[11]). Two important phenomena in communication are signal quantization and time delay. Unlike the error-free information exchange, the signals in real-world systems are required to be quantized before transmission when high data rate are not available. Some related results about network control system with quantized data have been reported in [8], [11]. In [8], robust $H_\infty$ estimation problems for uncertain systems subject to quantization are investigated. In [11], $H_\infty$ filter is designed for a class of nonlinear discrete time-varying stochastic systems with quantization effects. On the other hand, consensus problems with quantized data are also challenging and desired to be investigated. Discrete-time consensus protocols with quantization have been extensively studied (see [7], [9], [10], [12]–[14]).

Besides quantization, another significant communication constraint in multi-agent networks is the time delay, which is usually caused by an agent waiting to send out message via a busy channel, or by a signal processing and propagation [15]–[17]. It has been shown that conventional consensus protocol with time delay may lead to unexpected results [16].

From the viewpoint of both mathematics and engineering, it is worth noting that the quantization will lead to a system with no solutions in classical sense. Hence, considering solutions in a more general sense is necessary. A ground work have been laid in [18], which extend the quantized consensus model to the continuous-time case and quantized consensus results have been obtained for the network model. In this paper, we shall further extend the previous results of [18] by using different methods. Moreover, we shall address the consensus problems with consideration of the time delay and quantization simultaneously.

The main contributions of this paper are presented as follows:

- Two consensus protocols considering different communication constraints are proposed in this paper. The convergence analysis of the proposed protocols are discussed in detail.
- The effect of the time delay and quantization on the practical consensus set is obtained in this work.

The organization of the remaining part is given as follows. In Section II, some preliminaries about algebra graph theory and discontinuous differential equations are summarized. In Section III and IV, consensus analysis of the proposed protocol are presented in detail. In Section V, two numerical simulation examples are given to show the effectiveness of the theoretical results. In Section VI, concluding remarks are drawn.

$Notations$ : The standard notations will be used in this paper. Throughout this paper, $\mathbb{R}^n$ and $\mathbb{R}^{m\times n}$ represent $n$-dimensional Euclidean space and the set of $m\times n$ real matrices, respectively. $\mathbb{Z}$ denotes a set containing all integer numbers. The superscript "$T$" represents the transpose. $\lfloor\cdot\rfloor$ denotes the lower integer function. $[a, b]$ means the closed interval with endpoints $a$ and $b$. Let $\mathcal{C}([-\tau, 0]; \mathbb{R})$ denote the family of all

978-1-4673-1560-9/12/$31.00 ©2012 IEEE

continuous $\mathbb{R}$-valued functions $g(s)$ on $[-\tau, 0]$ with the norm $\|g(.)\| = sup_{-\tau \leq s \leq 0}|g(s)|$.

## II. Preliminaries and problem formulation

### A. Basic graph theory

Let $\mathcal{G}(\mathcal{V},\, \mathcal{E},\, \mathcal{A})$ be a *weighted directed graph* with the set of nodes $\mathcal{V} = \{v_1,\, v_2,\, \dots, v_N\}$, the set of edges $\mathcal{E} \subset \mathcal{V} \times \mathcal{V}$ and a weighted adjacency matrix $\mathcal{A} = [\bar{a}_{ij}]$ with nonnegative adjacency elements $\bar{a}_{ij}$. An edge of $\mathcal{G}$ is denoted by $e_{ij} = (v_i,\, v_j)$, where $v_i$ and $v_j$ are called the parent and child vertices, respectively. For adjacency matrix $\mathcal{A}$, $(v_i,\, v_j) \in \mathcal{E} \Longleftrightarrow \bar{a}_{ji} > 0$. For the undirected graph, one has $\bar{a}_{ij} = \bar{a}_{ji}$. The set of *neighbors* of $v_i$ in $\mathcal{G}$ is denoted by $\mathcal{N}_i(v_i) = \{v_j : (v_j,\, v_i) \in \mathcal{E}\}$. Let $A = \mathcal{A} - \Delta = [a_{ij}]$, where $\Delta = [\Delta_{ij}]_{N\times N}$ is a diagonal matrix with $\Delta_{ii} = \sum_{j=1}^{N} \bar{a}_{ij}$. Then, we have $a_{ij} = \bar{a}_{ij} \geq 0$ for $i \neq j$ and $a_{ii} = -\sum_{j=1,\, j\neq i}^{N} a_{ij}$. The matrix $-A$ is called the *Laplacian* of the directed graph. A *path* in a digraph is an ordered sequence of vertices such that any two consecutive vertices are an directed edge of the digraph. A directed graph $\mathcal{G}$ is *strongly connected* if there is a path for any pair of distinct vertices in $\mathcal{G}$.

### B. Discontinuous differential equations

For differential equations with discontinuous right-hand sides we understand the solutions in terms of differential inclusions following Filippov (1988).

Now we introduce the concept of Filippov solution. Consider the following system

$$\frac{d\mathbf{x}(t)}{dt} = f(\mathbf{x}(t)), \tag{1}$$

where $\mathbf{x} \in \mathbb{R}^n$, $f : \mathbb{R}^n \to \mathbb{R}^n$ is Lebesgue measurable and locally essentially bounded.

*Definition 1:* A set-valued map is defined as

$$\mathcal{K}(f(\mathbf{x})) = \bigcap_{\delta>0} \bigcap_{\mu(N)=0} \bar{co}[f(B(\mathbf{x}, \delta) \setminus N)], \tag{2}$$

where $\bar{co}(\Omega)$ is the closure of the convex hull of set $\Omega$, $B(\mathbf{x}, \delta) = \{y : \|y - \mathbf{x}\| \leq \delta\}$, and $\mu(N)$ is Lebesgue measure of set $N$. A solution in the sense of Filippov of the Cauchy problem for equation (1) with initial condition $\mathbf{x}(0) = \mathbf{x}_0$ is an absolutely continuous function $\mathbf{x}(t), t \in [0, T]$, which satisfies $\mathbf{x}(0) = \mathbf{x}_0$ and differential inclusion:

$$\frac{d\mathbf{x}}{dt} \in \mathcal{K}(f(\mathbf{x})), \quad a.e.\ t \in [0, T], \tag{3}$$

where $\mathcal{K}(f(\mathbf{x})) = (\mathcal{K}[f_1(\mathbf{x})], \cdots, \mathcal{K}[f_n(\mathbf{x})])$.

Let $h : \mathbb{R}^n \to \mathbb{R}$ be a locally Lipschitz function and $S_h$ be the set of points where $h$ fails to be differentiable. Clarke generalized gradient of $h$ at $\mathbf{x}$ is the set $\partial_c h(\mathbf{x}) = co\{\lim_{i\to+\infty} \nabla h(\mathbf{x}^{(i)}) : \mathbf{x}^{(i)} \to \mathbf{x},\, \mathbf{x}^{(i)} \notin S \cup S_h\}$, where $S$ can be any set of zero measure [19]. A Filippov solution to (3) is a maximal solution if it cannot be extended further in time.

## III. Finite-time Practical Consensus under the effects of quantization

Consider the following multi-agent system with dynamics

$$\dot{x}_i(t) = u_i(t), \quad i = 1, \dots, N,$$

where $x_i(t) \in R$ is the state of the agent $i$, and $u_i(t)$ is called the consensus protocol. The following consensus protocol

$$u_i(t) = \sum_{j\in\mathcal{N}_i} a_{ij}(x_j(t) - x_i(t)), \quad i = 1, \dots, N, \tag{4}$$

has been proposed in [1], which requires that each agent receives information from its neighbors timely and accurately.

Due to the communication bandwidth constraints in many real multi-agent networks, the agents can only use the quantized information of the neighboring agents. The following consensus protocol will be studied in this part.

$$\frac{dx_i(t)}{dt} = \sum_{j\in\mathcal{N}_i} a_{ij}[q_\mu(x_j(t)) - q_\mu(x_i(t))], \qquad i = 1, \dots, N, \tag{5}$$

where $q_\mu(z)$ denotes one-parameter family of uniform quantizers defined by $q_\mu(z) = \lfloor \frac{z}{\Delta\mu} + \frac{1}{2} \rfloor \mu$. Here, $\mu$ and $\Delta$ are called the *quantization parameters* and *error bound* of the quantizer, respectively. Moreover, if $\mathbf{x} = (x_1,\, x_2,\, ...,\, x_N)^T \in \mathbb{R}^N$, we denote $q_\mu(\mathbf{x}) = (q_\mu(x_1),\, q_\mu(x_2),\, ...,\, q_\mu(x_N))^T$.

We know that system (5) may not have the global solution in the sense of *Carathéodory* due to the discontinuous of function $q_\mu(.)$ [18]. Hence, we shall consider solutions in a more general sense, i.e, the Filippov solution of system (5). The concept of the Filippov solution to the differential equation (5) is as follows:

*Definition 2:* A absolutely continuous function $\mathbf{x} : [0,\, T) \to R^N$ is a solution in the sense of Filippov for the discontinuous system (5) if $\mathbf{x}$(t) satisfy that

$$\frac{dx_i(t)}{dt} \in \mathcal{K}[\sum_{j\in\mathcal{N}_i} a_{ij}(q_\mu(x_j(t)) - q_\mu(x_i(t)))], \quad i = 1, \dots, N.$$

Based on the measurable selection theorem of set-valued function (see [20], p. 308, Th. 8.1.3), if $\mathbf{x}(t)$ is a Filippov solution of system (5), then there exists a measurable function $\gamma(t) \in \mathcal{K}[q_\mu(\mathbf{x}(t)))]$ such that for almost all $t \in [0,\, T)$, the following equation is true:

$$\frac{dx_i(t)}{dt} = \sum_{j=1,\, j\neq i}^{N} a_{ij}(\gamma_j(t) - \gamma_i(t)), \qquad i = 1, \dots, N. \tag{6}$$

Any function $\gamma$ as in (6) is called an *output* associated to the solution $\mathbf{x}$.

*Remark 1:* Due to the introduction of the quantization effect, complete consensus cannot be ensured by the proposed protocol, but only *practical consensus* can be achieved. That is, the final consensus values lie within an interval, so called *practical consensus set*, as discussed in [18] and [21].

*Lemma 1:* Suppose $x(t)$ be a Filippov solution to (5). Let $\mathcal{N}=\{1,\ldots,N\}$, $M(t)=\max\limits_{i\in\mathcal{N}} x_i(t)$ and $m(t)=\min\limits_{i\in\mathcal{N}} x_i(t)$. Then, $M(t)$ is a non-increasing function for $t$ and $m(t)$ is a non-decreasing function for $t$.

*Proof:* The proof is similar to the one of Lemma 3, [22]. We omit here due to the length limit. ■

Let $\xi=\{\xi_1,\,\xi_2,\,\ldots,\,\xi_N\}$ be the normalized left eigenvector of matrix $A$ with respect to the zero eigenvalue satisfying $\sum\limits_{i=1}^{N}\xi_i = 1$. It can be obtained that $\xi_i > 0$ from Perron-Frobenius theorem (see [23]). Denote $\mathcal{N}=\{1,\ldots,N\}$ in the following part.

*Theorem 1:* Consider the multi-agent network (5) with a strongly connected graph $G$. The initial conditions associated with (5) are given as $x_i(0)$, $(i=1,2,\ldots,N)$. Let $k=\lfloor\frac{\sum_{i=1}^{N}\xi_i x_i(0)}{\mu\Delta}+\frac{1}{2}\rfloor$. Then $x_i(t)$ will converge to the set $\mathcal{D}=[(k-\frac{1}{2})\Delta\mu,\,(k+\frac{1}{2})\mu\Delta]$ for any $i\in\mathcal{N}$ in a finite time, where $\mu$ and $\Delta$ are quantization parameters and error bound of the quantizer.

*Proof:* The proof of Theorem 1 is divided into two parts.

Part (I) we shall take three steps to prove that each agent in the network will converge to a set $[(k-\frac{1}{2})\mu\Delta,\,(k+\frac{1}{2})\mu\Delta]$ in finite time.

Step 1. Consider the Lyapunov functional as

$$V(t)=\sum_{i=1}^{N}\xi_i\int_0^{x_i(t)} q_\mu(s)ds. \tag{7}$$

Note that $cq_\mu(c)\geq 0$ for any $c\in\mathbb{R}$, we have $V(t)\geq 0$.

Notice that for $p_i(s)=\int_0^s q_\mu(u)du$, we have $\partial p_i(s)=\{v\in\mathbb{R}: q_\mu^-(s)\leq v\leq q_\mu^+(s)\}$. Based on the chain rule (for details, see Proposition 6, [24]), $V(t)$ is differentiable for a.e. $t\geq 0$. Differentiating $V(t)$ along the solution of (6) gives that

$$\begin{aligned}\frac{dV(t)}{dt} &= \sum_{i=1}^{N}\xi_i\gamma_i(t)\sum_{j=1,\,j\neq i}^{N}a_{ij}[\gamma_j(t)-\gamma_i(t)]\\ &= \frac{1}{2}\sum_{i=1}^{N}\sum_{j=1,\,j\neq i}^{N}\xi_i a_{ij}[2\gamma_i(t)\gamma_j(t)-2\gamma_i^2(t)].\end{aligned} \tag{8}$$

Notice that

$$\begin{aligned}&\sum_{i=1}^{N}\sum_{j=1,\,j\neq i}^{N}\xi_i a_{ij}\gamma_i^2(t)=\sum_{i=1}^{N}(-a_{ii})\xi_i\gamma_i^2(t)\\ &=\sum_{j=1}^{N}(-a_{jj})\xi_j\gamma_j^2(t)=\sum_{j=1}^{N}\sum_{i=1,\,i\neq j}^{N}\xi_i a_{ij}\gamma_j^2(t)\\ &=\sum_{i=1}^{N}\sum_{j=1,\,j\neq i}^{N}\xi_i a_{ij}\gamma_j^2(t),\end{aligned} \tag{9}$$

we have

$$\frac{dV(t)}{dt}=-\frac{1}{2}\sum_{i=1}^{N}\sum_{j=1,\,j\neq i}^{N}\xi_i a_{ij}(\gamma_i(t)-\gamma_j(t))^2. \tag{10}$$

Step 2. Let $\Phi=\{\mathbf{x}(t)\in\mathbb{R}^N :\mid\gamma_i(t)-\gamma_j(t)\mid<\frac{\mu}{N+1},\ \forall i,\,j\in\mathcal{N},\,i\neq j,\,a_{ij}\neq 0\}$. We claim that the agents in the network converge to the set $\Phi$ in finite time.

Let $J=\{t\geq 0:\mathbf{x}(t)\notin\Phi\}$. For $\mathbf{x}(t)\in\mathbb{R}^N$ and $t\in J$, there exist $i,\,j\in\{1,\,2,\,\ldots,\,N\}$, $i\neq j$ and $a_{ij}\neq 0$ such that $\mid\gamma_i(t)-\gamma_j(t)\mid\geq\frac{\mu}{N+1}$. Hence, for $a.e.\,t\in J$

$$\begin{aligned}\dot{V}(t) &\leq -\frac{1}{2}\xi_i a_{ij}(\frac{\mu}{N+1})^2\\ &\leq -\frac{1}{2}\zeta\mu^2,\end{aligned} \tag{11}$$

where $\zeta=\min\limits_{1\leq i,\,j\leq N,\,a_{ij}>0}[(\frac{1}{N+1})^2 a_{ij}\xi_i]$. Further, we can obtain

$$\begin{aligned}0 &\leq V(t)\\ &\leq V(0)-\frac{1}{2}\zeta\mu^2 t,\ t\geq 0.\end{aligned} \tag{12}$$

It follows from $V(0)\geq 0$ that (12) holds if and only if $t\leq\frac{2V(0)}{\zeta\mu^2}$. Therefore, $\mathbf{x}(t)$ will arrive to the set $\Phi$ in finite time.

Step 3. we shall prove that there exists $k\in\mathbb{R}$ such that $x_i(t)$ will converge to the set $[(k-\frac{1}{2})\mu\Delta,\,(k+\frac{1}{2})\mu\Delta]$ in finite time for every $i\in\mathcal{N}$.

Note that $\gamma_i(t)\in\mathcal{K}[q_\mu(x_i(t))]$ and $\gamma_j(t)\in\mathcal{K}[q_\mu(x_j(t)]$, we can get that there exist $k_{ij}\in\mathbb{R}$ such that $x_i(t)$ and $x_j(t)$ belong to the set $[(k_{ij}-\frac{1}{2})\mu\Delta,\,(k_{ij}+\frac{1}{2})\mu\Delta]$ if $\mid\gamma_i(t)-\gamma_j(t)\mid<\frac{\mu}{N+1}$. Hence, based on the proof of step 2, there exists a $T_0\geq 0$ such that $\forall i,\,j\in\mathcal{N},\,i\neq j,\,a_{ij}\neq 0,\,x_i(T_0)$ and $x_j(T_0)$ belong to the set $[(k_{ij}-\frac{1}{2})\mu\Delta,\,(k_{ij}+\frac{1}{2})\mu\Delta]$. Due to the network is strongly connected, there exists a $k\in\mathbb{R}$ such that $k_{ij}=k$.

It follows from Lemma 1 that $x_i(t)\in[(k-\frac{1}{2})\mu\Delta,\,(k+\frac{1}{2})\mu\Delta]$ for $\forall i\in\mathcal{N}$, $t\geq T_0$.

Part (II) Estimate the value of $k$.

Up till now, we have proved the first part of the Theorem 1. Next, we shall give the value of $k$ which is shown to be depending on the initial values of the multi-agent network. Let $\eta(t)=\sum_{i=1}^{N}\xi_i x_i(t)$. We can calculate the derivative of $\eta(t)$ as follows:

$$\begin{aligned}\dot{\eta}(t) &= \sum_{i=1}^{N}\xi_i\sum_{j=1,\,j\neq i}^{N}a_{ij}[\gamma_j(t)-\gamma_i(t)]\\ &= \sum_{i=1,\,i\neq j}^{N}\xi_i a_{ij}\sum_{j=1}^{N}\gamma_j(t)-\sum_{i=1}^{N}\xi_i\gamma_i(t)\sum_{j=1,\,j\neq i}^{N}a_{ij}\\ &= -\sum_{j=1}^{N}\xi_j a_{jj}\gamma_j(t)+\sum_{i=1}^{N}\xi_i a_{ii}\gamma_i(t)\\ &= 0.\end{aligned}$$

Due to $\dot{\eta}(t)=0$ for a.e. $t\in[0,\,\infty)$ and the continuity of $\eta(t)$, it can be easily obtained that $\eta(t)$ is a constant. That is, $\eta(t)=\eta(0)=\sum_{i=1}^{N}\xi_i x_i(0)$.

Next, we need to estimate the value of $k$. Let $\mathcal{D}=[(k-\frac{1}{2})\mu\Delta,\,(k+\frac{1}{2})\mu\Delta]$, we have proved that there exists a $T_0$ such that $x_i(t)\in\mathcal{D},\quad\forall t\geq T_0,\quad\forall i\in\mathcal{N}$.

It follows from $\sum_{i=1}^{N}\xi_i = 1$ that $\sum_{i=1}^{N}\xi_i x_i(t) \in \mathcal{D}, \quad \forall t \geq T_0$. Thus, $\sum_{i=1}^{N}\xi_i x_i(0) \in [(k-\frac{1}{2})\mu\Delta, (k+\frac{1}{2})\mu\Delta]$.

We consider the following two cases:

Case 1: If there exists a $k_0 \in \mathbb{Z}$ such that $\sum_{i=1}^{N}\xi_i x_i(0) = (k_0 - \frac{1}{2})\mu\Delta$, then $k = k_0$ or $k_0 - 1$. Since $x_i(t) \in \mathcal{D}, \quad \forall t \geq T_0, \quad \forall i \in \mathcal{N}$, we have $x_i(t) = (k_0 - \frac{1}{2})\mu\Delta, \quad \forall t \geq T_0$. In this case, we can select $k = k_0$. That is, $k = \frac{1}{\mu\Delta}\sum_{i=1}^{N}\xi_i x_i(0) + \frac{1}{2} = \lfloor \frac{1}{\mu\Delta}\sum_{i=1}^{N}\xi_i x_i(0) + \frac{1}{2}\rfloor$.

Case 2: If $\sum_{i=1}^{N}\xi_i x_i(0) \neq (k_0 - \frac{1}{2})\mu\Delta$ for any $k \in \mathbb{Z}$, then, $\sum_{i=1}^{N}\xi_i x_i(0) \in ((k-\frac{1}{2})\mu\Delta, (k+\frac{1}{2})\mu\Delta)$. Hence, $k = \lfloor \frac{1}{\mu\Delta}\sum_{i=1}^{N}\xi_i x_i(0) + \frac{1}{2}\rfloor$.

Therefore, $k = \lfloor \frac{1}{\mu\Delta}\sum_{i=1}^{N}\xi_i x_i(0) + \frac{1}{2}\rfloor$. This completes the proof of this theorem. ■

*Remark 2:* As discussed in the Theorem 2 and Proposition 4 of [18], the practical consensus results for the model (5) with $\Delta = 1$ are investigated via LaSalle invariance principle of differential inclusions. While in this paper, using different methods, we extend the previous results from the following three aspects:

- We do not assume the network is undirected or balanced.
- We show that the Filippov solutions of (5) reach set $\mathcal{D} = [(k-\frac{1}{2})\mu, (k+\frac{1}{2})\mu]$ in a finite time even if $x_{ave}(0) = \frac{1}{N}\sum_{i=1}^{N} x_i(0) = (k_0 + \frac{1}{2})\mu$ for some $k_0 \in \mathbb{Z}$.
- We present an explicit relationship between the practical consensus set and initial conditions.

*Corollary 1:* Consider the multi-agent network (5) with a strongly connected graph $G$. The initial conditions associated with (5) are given as $x_i(0), (i = 1, 2, \ldots, N)$. Let $k = \lfloor \frac{1}{\mu\Delta}\sum_{i=1}^{N}\xi_i x_i(0) + \frac{1}{2}\rfloor$. Then $x_i(t)$ will converge to the set $\Omega = [\sum_{i=1}^{N}\xi_i x_i(0) - \mu\Delta, \sum_{i=1}^{N}\xi_i x_i(0) + \mu\Delta]$ in a finite time, where $\mu$ and $\Delta$ are quantization parameters and error bound of the quantizer.

*Proof:* According to Theorem 1, $x_i(t)$ converges to the set $[(k-\frac{1}{2})\mu\Delta, (k+\frac{1}{2})\mu\Delta]$ in a finite time, where $k = \lfloor \frac{1}{\mu\Delta}\sum_{i=1}^{N}\xi_i x_i(0) + \frac{1}{2}\rfloor$. It follows from $\sum_{i=1}^{N}\xi_i x_i(0) - \frac{1}{2}\mu\Delta \leq k\mu\Delta \leq \sum_{i=1}^{N}\xi_i x_i(0) + \frac{1}{2}\mu\Delta$ that $x(t)$ will converge to the set $\Omega = [\sum_{i=1}^{N}\xi_i x_i(0) - \mu\Delta, \sum_{i=1}^{N}\xi_i x_i(0) + \mu\Delta]$ in a finite time. ■

*Remark 3:* From Corollary 1, how the initial condition of the agents and quantization parameter $\mu$ affect the practical consensus set $\Omega$ can be observed explicitly. It is interesting to observe that the size of the practical consensus set can be made arbitrarily small by decreasing the quantization parameter $\mu$.

## IV. Practical consensus under quantization and time delay

Considering time delay as another very important communication constraint in the process of information exchange, we propose the following practical consensus protocol:

$$\frac{dx_i(t)}{dt} = \sum_{j\in\mathcal{N}_i} a_{ij}[q_\mu(x_j(t-\tau)) - q_\mu(x_i(t))], \qquad i = 1, \ldots, N, \qquad (13)$$

where $\tau$ is the communication delay from agent $j$ to agent $i$ and $q(.)$ is the same as in model (5). The initial conditions associated with (13) are given as $x_i(s) = \phi_i(s) \in \mathcal{C}([-\tau, 0], R) \quad (i = 1, 2, \ldots, N)$.

Next, we will present the the Filippov solution of system (13).

*Definition 3:* A function $\mathbf{x} : [-\tau, T) \to R^N$ ($T$ might be $\infty$) is a solution in the sense of Filippov for the discontinuous system (13) on $[-\tau, T)$, if

1) $\mathbf{x}$ is continuous on $[-\tau, T)$ and absolutely continuous on $[0, T)$;
2) $\mathbf{x}$(t) satisfy that

$$\frac{dx_i(t)}{dt} \in \mathcal{K}[\sum_{j\in\mathcal{N}_i} a_{ij}(q_\mu(x_j(t-\tau)) - q_\mu(x_i(t)))], \quad i = 1, \ldots, N. \qquad (14)$$

It follows from Theorem 1 in [25] that

$$\mathcal{K}[\sum_{j\in\mathcal{N}_i} a_{ij}(q_\mu(x_j(t-\tau)) - q_\mu(x_i(t)))] \subseteq \sum_{j\in\mathcal{N}_i} a_{ij}(\mathcal{K}[q_\mu(x_j(t-\tau))] - \mathcal{K}[q_\mu(x_i(t))]). \qquad (15)$$

Similar to (6), if $\mathbf{x}(t)$ is the solution of system (13), then there exists a measurable function $\gamma(t) \in \mathcal{K}[q_\mu(\mathbf{x}(t)))]$ such that for a.e. $t \in [0, T)$, the following equation is true:

$$\frac{dx_i(t)}{dt} = \sum_{j=1}^{N} a_{ij}(\gamma_j(t-\tau) - \gamma_i(t)), \quad i = 1, \ldots, N. \qquad (16)$$

Now, we shall present the definition of an initial value problem associated to (13).

*Definition 4:* For any continuous function $\phi : [-\tau, 0] \to \mathbb{R}^N$ and any measurable selection $\psi : [-\tau, 0] \to \mathbb{R}^N$, such that $\psi(s) \in \mathcal{K}[q_\mu(\phi(s))]$ for a.e. $s \in [-\tau, 0]$, an absolute continuous function $\mathbf{x}(t) = \mathbf{x}(t, \phi, \psi)$ is said to be a solution of Cauchy problem for system (13) on $[0, T)$ with initial value $(\phi, \psi)$, if

$$\begin{cases} \dot{x}(t) = \sum_{j=1}^{N} a_{ij}(\gamma_j(t-\tau) - \gamma_i(t)) \\ for\ \ a.e.\ t \in [0, T), \quad i = 1, \ldots, N, \\ \mathbf{x}(s) = \phi(s), \quad \forall s \in [-\tau, 0], \\ \gamma(s) = \psi(s) \quad a.e. \quad s \in [-\tau, 0]. \end{cases} \qquad (17)$$

Note that the solution of the system (17) depends on the initial function $\phi$ and also on the selection of the output $\psi(s) \in \mathcal{K}[q_\mu(\phi(s))]$. In the following part, we shall show that the global solution for system (17) exists. The proof is omitted here due to the length limit.

*Theorem 2:* For any initial function $\phi$ and the selection of the output $\psi(s) \in \mathcal{K}[q_\mu(\phi(s))]$, there exists the global solution for system (17).

Next, we shall present the consensus result under the effects of quantization and time delay simultaneously. The proof will be presented in the full-length version of the paper. The initial conditions associated with (5) are given as $x_i(s) = \phi_i(s) \in \mathcal{C}([-\tau, 0], \mathbb{R}), \quad (i = 1, 2, \ldots, N)$. The Filippov solution of

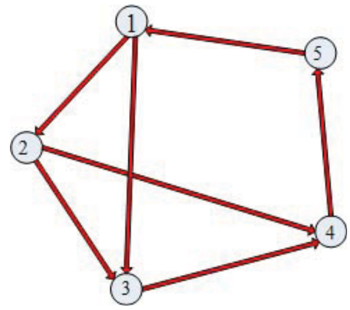

Fig. 1. Network topology in Example 1.

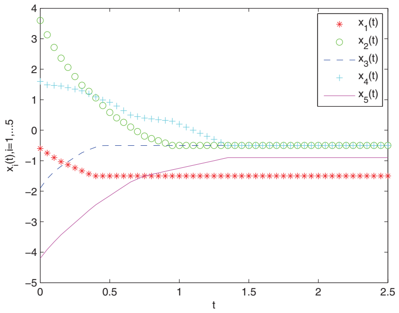

Fig. 2. The states of the multi-agent network in Example 1.

system (13) is defined in (17) and $\psi_j(s)$ $(s \in [-\tau, 0])$ is the initial condition of measurable selection of $\gamma_j(s)$. Let $\eta(0) = \frac{1}{N}\sum_{i=1}^{N} x_i(0) + \frac{1}{N}\sum_{i=1}^{N}\sum_{j=1,\, j\neq i}^{N} a_{ij}\int_{-\tau}^{0}\psi_j(s)ds$ and $A = \mu(\Delta - \frac{\tau}{N}\sum_{i=1}^{N} a_{ii})$, where $\mu$ and $\Delta$ are quantization parameters and error bound of the quantizer.

*Theorem 3:* Consider the undirected multi-agent network (13) with connected graph $G$. Then, for any finite communication delay $\tau$, each agent in the network will converge to the set of $\Omega_1 = [(k-\frac{1}{2})\mu\Delta,\ (k+\frac{1}{2})\mu\Delta]$ asymptotically, where $k = \lfloor\frac{\eta(0)}{A}\rfloor$ or $\lfloor\frac{\eta(0)}{A}\rfloor + 1$.

## V. Numerical examples

In this section, two examples are given to illustrate the correctness of the theoretical results.

*Example 1:* Consider the multi-agent system (5) with five agents, where $\mu = 1$ and $\Delta = 1$. The directed network topology is displayed in Figure 1, and the weight of each edge is set as 1.

Figure 2 shows the state trajectories of (5) with the initial condition randomly chosen from (-5,5). It can be observed from Figure 1 that the state of each agent converges to a practical consensus set in a finite time, which illustrates Theorem 1 very well.

In many real multi-agent consensus problems, the size of this consensus set is required to be very small. In the following example, we will show that the size of the practical consensus set can be reduced by decreasing the quantization parameter $\mu$, which also illustrates Corollary 1 well.

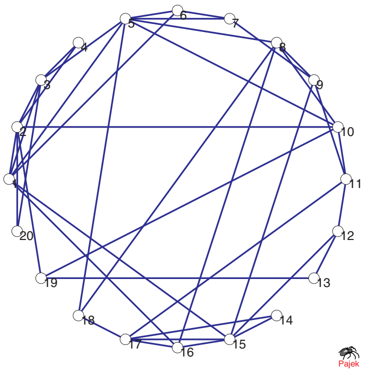

Fig. 3. Network topology in Example 2.

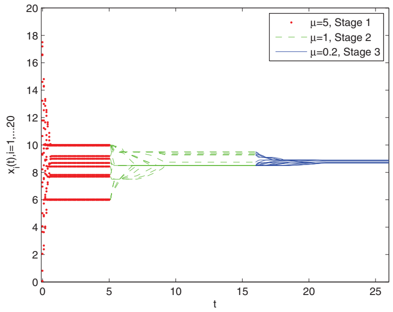

Fig. 4. The states trajectories of the multi-agent networks at different stages with respect to different $\mu$.

*Example 2:* In order to illustrate how quantization parameter $\mu$ affects the practical consensus set and how to reduce the size of the practical consensus set, a multi-agent network (5) with 20 agents is considered. The graph (Figure 3) is assumed to be a small-world network (undirected), in which each node has 2 nearest neighbors and the rewiring probability of the edges is 0.5 (see [26]). Let $\Delta = 1$ and initial conditions are randomly chosen from (0,20). Let the quantization parameter $\mu$ be updated at each stage of practical consensus:

$$\mu = \begin{cases} 5, & 5 > t \geq 0\ (Stage\,1), \\ 1, & 16 > t \geq 5,\ (Stage\,2) \\ 0.2, & 42 > t \geq 16\ (Stage\,3). \end{cases} \tag{18}$$

Note that the value of parameter $\mu$ is reduced by $80\%$ after each stage of practical consensus in order to reduce the size of the consensus set.

Figure 4 shows the states of the 20 agents at different stages with respect to $\mu = 5$, $1$ and $0.2$, respectively. At each stage, all the agents converge to a practical consensus set in a finite time. After a smaller value of $\mu$ is chosen, the agents converge to a new set with a smaller range. The final consensus states of the 20 agents at different stages are respectively shown in Figure 5. From Figures 4 and 5, we can observe that the size of the consensus set is greatly reduced as $\mu$ decreases at different stages. These two figures also verify Corollary 1, that is, the size of consensus set is controlled by $\mu$.

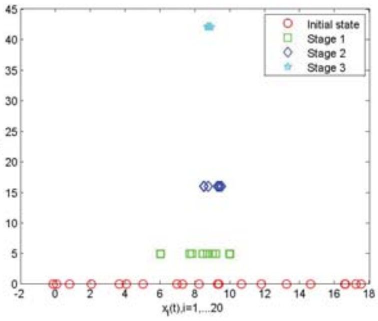

Fig. 5. The final states of the 20 agents at different stages with respect to different $\mu$.

## VI. Conclusion

This paper investigates the continuous-time consensus problem of multi-agent network where each agent can only obtain the quantized and delayed measurements of the states of its neighbors. Filippov solutions of the resulting system exist for any initial condition. We have proved that under certain network topology, the states of the multi-agent network which only considers quantization effect will converge to a practical consensus set in a finite time. For the multi-agent network model considering quantization and time delay simultaneously, it is shown that Filippov solutions converge to a practical consensus set asymptotically. Moreover, we also present how initial state of the agents, time delay and quantization parameter affect the final practical consensus set. The theoretical results have been well illustrated by two numerical examples.

***Abstract*—A novel smooth second-order sliding mode (SSOSM) control is applied to tackle the problem of PEM fuel cell system output voltage stabilization along with controlling oxygen excess ratio. The oxygen excess ratio is controlled in the inner control loop using PID while the regulation of output voltage is being treated in the outer loop through smooth second-order sliding mode control. The control is applied on the validated nonlinear model of the PEM fuel cell system. The simulation results show that the scheme with SSOSM control provides smoothness (chattering free) with robust performance and the fuel consumption minimization.**

## I. INTRODUCTION

Petroleum is a fossil fuel and is obtained from the earth's resource of fossil which are finite. The current trend of petroleum consumption is highly increasing with respect to new explorations. If the oil discovery and consumption follow the current trends, estimation shows that the world oil reserves will hardly be used by 2038. Transportation sector is the main user of petroleum and is growing very fast specially in developing countries. This trend needs to optimal use of petroleum with improved efficiency and also require to switch to alternate energy resources.

Fuel cell is a promising alternate energy resource with zero emission environment friendly technology and recent researches in this area show that fuel cell is capable in wide range of application as power source. Different types of fuel cells are suitable for different applications. Polymer Electrolyte Membrane Fuel Cell (PEMFC) shows its potential in, stationary, portable and specially propulsion applications and now in the phase of commercialization.

Fuel Cell System is an electrochemical device that converts chemical energy into electricity directly. Hydrogen and oxygen are its inputs as fuel and oxidant respectively. The voltage is its output which doesn't inherit stabilized form. The voltage varies due to chemical reactions and fluid dynamics. It also degrades due to increase in the load. The variable and degraded voltage is not useful for all electric appliances because they need regulated voltage for their proper working and their long life. That is why; the stabilization of output voltage is a challenging problem for researchers.

The desired output voltage can be maintained through an effective control system. The controller can stabilize the voltage efficiently manipulating inputs. This manipulation can made the system economical avoiding conservative use of inputs. A typical propulsion system based on PEM fuel cell is shown in Fig. 1.

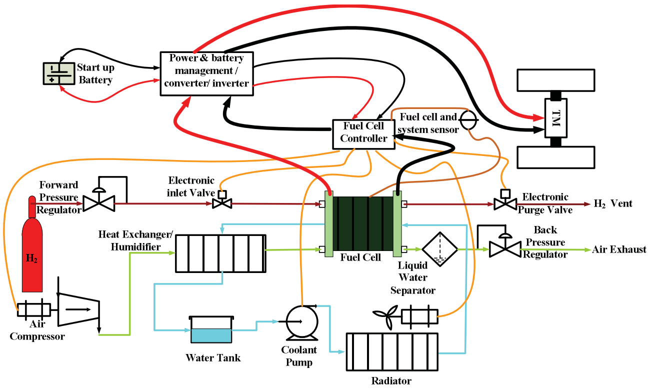

Figure 1. PEM Fuel Cell System for Propulsion

Most of the vast literature available on fuel cells deals with the steady-state conditions. Many researchers attempted to develop electrochemistry based models of PEM fuel cell [8, 9]. The work presented by Lu Ying Chiu and Tanrioven is aimed at developing dynamic models of PEM fuel cell [10, 11]. The dynamic model and design of combined fuel cell and ultra-capacitor system for stand-alone residential applications is developed in [12].

Some models focused on the description of the fuel cell stack and formed the basis for many 2D and 3D finite element models that allow predicting local reactant concentration, temperature and current density [13-15]. Kim et al, Lee et al, and Mann et al proposed generic models that can be adjusted to any fuel cell by adjusting a certain number of fitting parameters [16-18]. Rodatz developed a one dimensional, steady state fuel cell model. Based on stack temperature, current, anode and cathode humidity and pressures, it describes the cell voltage [19].

Although these models provide certain understanding of PEM fuel cell, they cannot be used to perform control algorithm development for PEM fuel cell system. Such models were intended for simulation or parameter estimation rather

This work is supported by Higher Education Commission (HEC) of Pakistan.

978-1-4673-1560-9/12/$31.00 ©2012 IEEE

than control analysis. Other PEM fuel cell models available in the open literature cannot be used for simulations and control purposes because the information about the parameters was not listed completely. Some of them were incomplete and too complex as well as computationally intensive to be used for real-time applications. To develop refined control strategies for PEM fuel cell system, an accurate mathematical model of PEM fuel cell system is necessary.

In this wok, a dynamic non-linear mathematical model for 500Watt PEM fuel cell [6, 7], is used. This model describes the parameters that have a physical significance so that it can be adapted to a given system. It describes correctly the interaction between the different subsystems from a controls point of view. The results of the non-linear PEM fuel cell model simulation in the Simulink/Matlab environment ensure the perfectness of the Model.

The Avista SR-12 system is designed to produce power up to 500Watt (25V at 20A). The specifications of the SR-12 system, as provided by Avista [20], are shown in Appendix C [37].

In this work, PEM fuel cell model is studied in section II and a proposed scheme is developed in section III, controller synthesis and their stability proof along with simulation results for verification is provided in section IV, and then the final conclusion.

## II. PEM Fuel Cell Model

The block diagram in Fig. 2 describes the relationship developed in mathematical model. The model has three inputs hydrogen pressure, oxygen pressure, disturbance load current and an exogenous input i.e. room temperature whereas it has only two outputs fuel cell voltage and stack temperature. The partial pressures of hydrogen, oxygen and water vapors are calculated by mass balance and material conservation equations. Then, the open circuit potential ($V_{OFC}$) of the fuel cell is determine by the Nernst equation. The voltage losses are calculated by ohmic voltage drop equation, activation voltage drop equations and concentration voltage drop equations. The terminal (output) voltage of the fuel cell is determined by voltage losses together with the double-layer charging effect equation. The thermodynamic equations are used to calculate stack temperature.

The states description of non-linear fuel cell system model [37] is as follows:

$x_1 = \left(m_{O_2\_net}\right)_{net}$ Net flow rate of Oxygen (mol/s)

$x_2 = \left(m_{H_2\_net}\right)_{net}$ Net flow rate of Hydrogen (mol/s)

$x_3 = \left(m_{H_2O\_net}\right)_{net}$ Net flow rate of Water (mol/s)

$x_4 = T$ Stack temperature (K)

$x_5 = P_{H_2}$ Partial pressure of hydrogen (atm)

$x_6 = P_{O_2}$ Partial pressure of oxygen (atm)

$x_7 = P_{H_2O}$ Partial pressure of water (atm)

$x_8 = Q_C$ Heat generated due to electrochemical reaction (J)

$x_9 = Q_E$ Heat generated due to electricity (J)

$x_{10} = Q_L$ Heat loss by air Convection (J)

$x_{11} = V_c$ Voltage across the Capacitor (V)

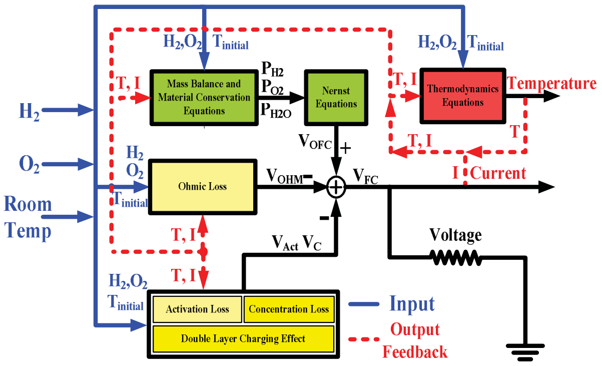

Figure 2. Block Diagram of PEM Fuel Cell Model

The V-I and P-I characteristic curves obtained in [37] of PEM fuel cell model is presented in Fig. 3.

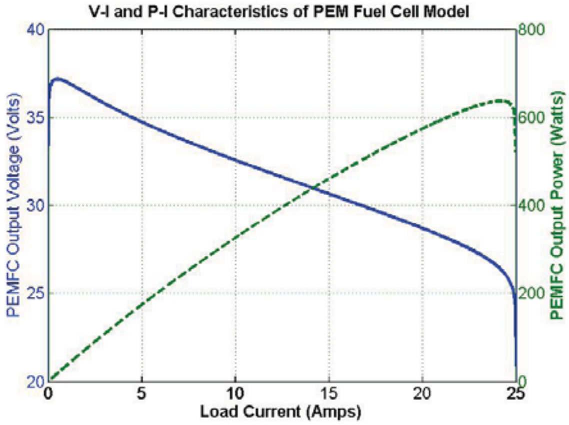

Figure 3. V-I & P-I Characteristics of PEM Fuel Cell Model

## III. Problem Formulation

The strategy contains two control loops. The first loop tries to maintain the stoichiometric oxygen excess ratio whereas the second loop stabilizes the output voltage of the system as shown in Fig. 4. The basic problem with the operation of fuel cell system is that it does not produce steady output voltage whereas most of the electrical appliances require stable one. There is a variation in the output voltage as the load varies and it drops with the passage of time even if the fuel supply is kept steady. It may conclude that to get rid of variable and degraded output voltage, there is an inevitable need of voltage stabilization.

The rapid and efficient control of air flow is required for avoiding oxygen starvation and the life of the stack [24]. The purpose of sustaining the excess ratio is to optimize the conversion of energy in the fuel cell and maximize the net power by the system operating under different load conditions, while minimizing the parasitic losses of feeding more oxygen into the cathode. If during the operation, the partial pressure of oxygen in the air stream of the cathode falls down to a certain critical level, a complicated phenomenon called oxygen starvation occurs [25].This phenomenon causes a sudden decrease in fuel cell output voltage, which can causes a hot spot or even burn the surface of a membrane in some severe situations [26].The sufficient mass flow of oxygen through the stack will satisfy the load demand. In this way not only the fuel consumption is minimized but also oxygen starvation will be avoided. The optimal mass flow of oxygen is achieved by maintaining the oxygen excess ratio to its optimal value at cathode. The stoichiometric ratio or the oxygen excess ratio is defined as [27].

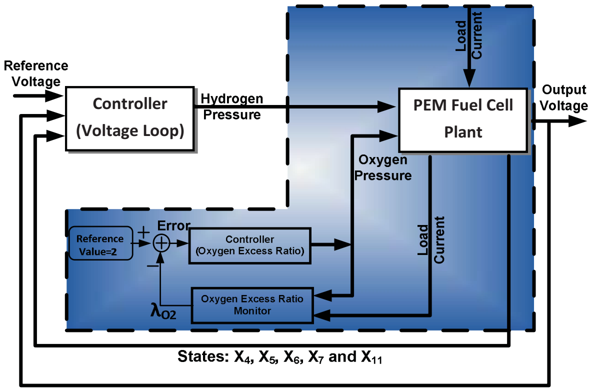

Figure 4. Control Scheme for PEM Fuel Cell System

$$\lambda_{O_2} = \frac{m_{O_2 in}}{m_{O_2 used}} \tag{1}$$

Where $m_{O_2 in}$ is the number of moles of oxygen going into the cathode, which depends on the pressure generated by the air blower and the vapors injected by the humidifier, while $m_{O_2 used}$ is the number of moles of oxygen consumed in the reaction. The total stack current depends upon this rate of oxygen consumption.

The optimum value of oxygen excess ratio is estimated by varying load to the stack on different values of stoichiometry operating as open-loop system [28]. It depends on the load condition and is normally taken as two which can be clearly seen from Fig. 5 that at higher load current, the peak power can be obtained at $\lambda_{O_2} = 2$ before and after that point, it decreases. Many fuel cell systems exhibits the same behavior with some ignorable deviations in the system operating range so $\lambda_{O_2}$ can be kept constant. Otherwise, variable $\lambda_{O_2}$ can easily be derived as a function of load current.

The advantage of the oxygen excess ratio control is to avoid oxygen starvation on the cathode side that can causes serious problems to the polymer membrane's life; the control will allow the oxygen to go below when it is needed [28, 29]. Another significance of maintaining oxygen excess ratio is that it maximizes or optimizes performance, efficiency and lifetime of the fuel cell.

On the other hand if the oxygen excess ratio crosses the optimal value then extra amount of energy is required to pump the oxygen into the cathode while the fuel cell system output power also degrades. Once the optimized stoichiometric ratio is obtained then keeping the oxygen excess ratio within optimal values by controlling the oxygen molar flow rate can be written as.

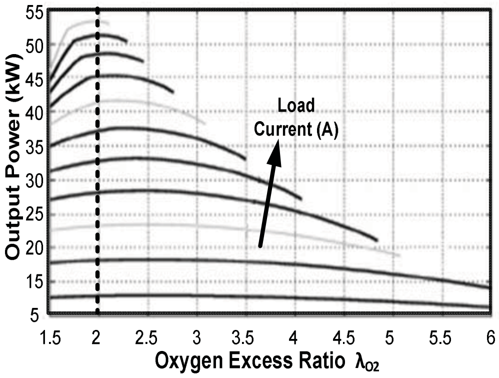

Figure 5. Analysis of oxygen excess ratio on net output power at different load conditions [28]

$$\lambda_{O_2} = \frac{4F8.614x10^{-5}U_{pc}}{n_s\, I} \cong 2 \tag{2}$$

The output voltage stabilization is carried out via five different approaches i.e. Proportional, Integral and Derivative (PID) control, first order SMC, Higher Order Sliding Mode (HOSM) control using super twisting algorithm [37], Smooth Sliding Mode Control (SSMC) [38] and Smooth Second Order Sliding Mode Control. The simulation experiments are performed on a nonlinear state space mathematical model that is validated with experimental results available in public literature.

## IV. Controller Design

### A. PID Control

To regulate the oxygen excess ratio a Proportional Differential and Integral (PID) controller is used. The reasons for selecting PID controller is that it is a simple controller and it can serve the particular task well without moving forward to advanced complicated robust controllers.

The control law for PID controller is given as:

$$U = K_p\, e + K_i \int e\, dt + K_d \frac{d}{dt} e \tag{3}$$

The PID controller is stabilizing the oxygen excess ratio at optimum value that is two in the presence of external varying

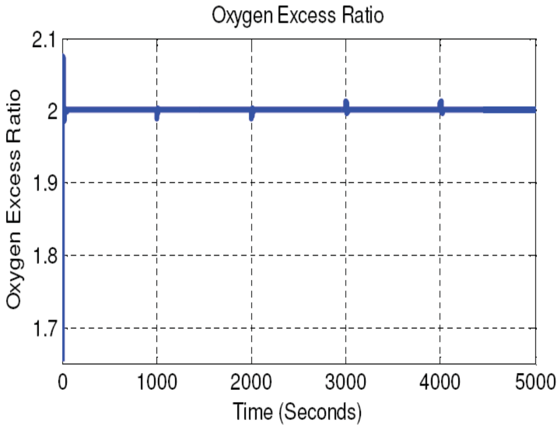

Figure 6. Controlled oxygen excess ratio

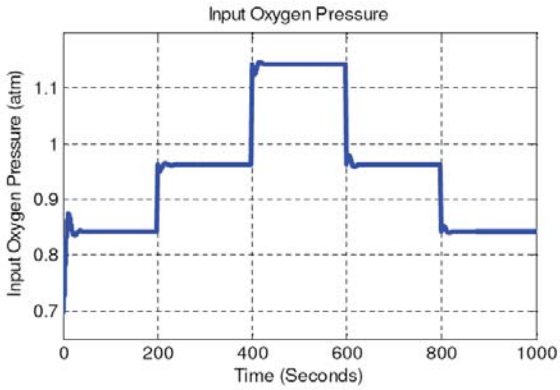

Figure 7. Input Oxygen Pressure (PID)

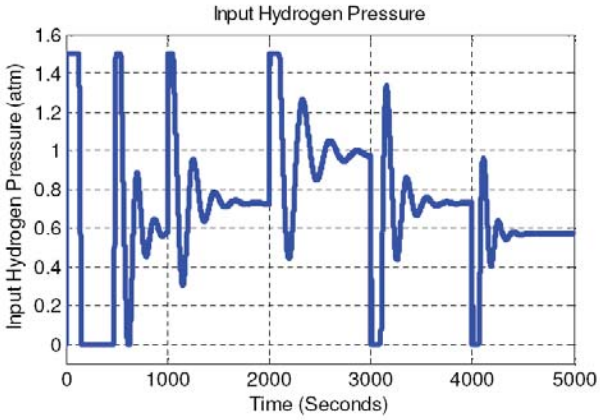

Figure 8. Input Hydrogen Pressure (PID)

disturbance. There are little over shots and under shots after each 1000 seconds interval. This is due to the step variation in the load current as in Fig. 6. This band of variation is bearable for the plant.

Controlled input oxygen pressure formed by the PID controller on oxygen excess ratio loop in order to maintain the oxygen excess ratio at 2. Oxygen excess ratio is maintained at an optimal value by an oxygen excess ratio controller as shown in Fig. 7. Oxygen excess ratio is regulating pretty well at optimal value via PID controller. A PID controller is applied on the voltage loop of the fuel cell to track the reference voltage in the presence of the oxygen excess ratio as shown in Fig. 9 and Fig. 8 represents the control effort generated by the PID controller to stabilize the fuel cell output voltages by manipulating input hydrogen pressure. The oscillations is because of the variation in load current. The settling time for the PID is high. The Fig. 10 shows error in the output voltage of the fuel cell; in ideal case error should be zero. The variations in the error are due to the load current variations on the output of fuel cell.

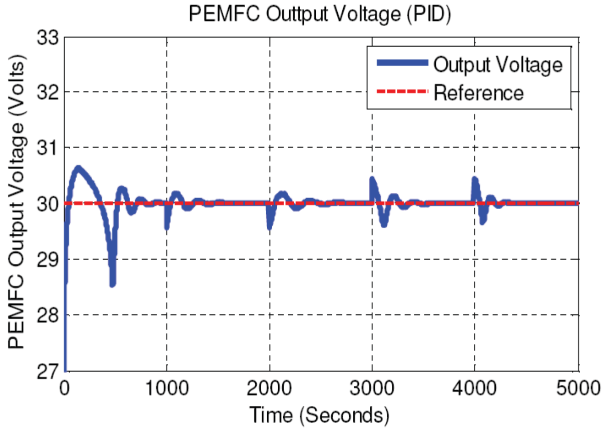

Figure 9. PEM Fuel Cell Output Voltage (PID)

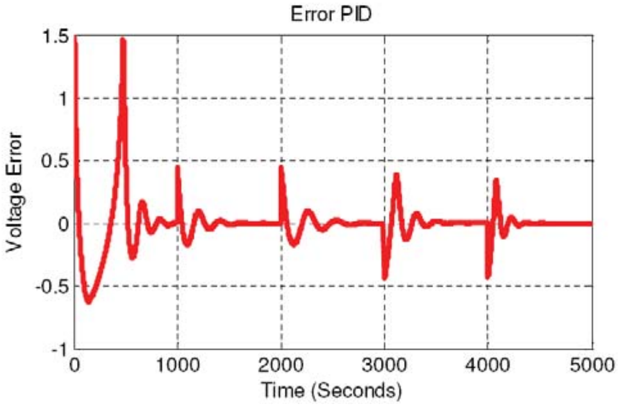

Figure 10. PID Output Voltage Error

## B. Smooth Second Oder Sliding Mode Control

A Higher-order Smooth Sliding Mode Control (HSSMC)/ Smooth Second-Order Sliding Mode Control (SSOSMC) strategy is investigated for Proton Exchange Membrane Fuel Cell (PEMFC) system to achieve the smoothness in control law. In this strategy first loop tries to maintain the stoichiometric ratio whereas the second loop stabilizes the output voltage of the system.

Smooth Second Order Sliding Mode Control is synthesized as follows. Consider SISO $\sigma$ –dynamics

$$\dot{\sigma} = g(t) + u \tag{4}$$

Where $\sigma$ is the sliding surface, the uncertainty *g(t)* is a smooth function and $u \in \Re$ is a control input. The sliding variable $\sigma$ is the system motion along the system trajectories and $\sigma = 0$ is the system motion on the sliding surface. The smoothness in the control input $u$ is the main objective of this synthesis. This synthesized control law $u$ pushes the sliding variable and its derivative to zero, i.e. $\sigma, \dot{\sigma} \rightarrow 0$ in finite time. In this technique, by using Levant exact differentiator based observer, the drift term *g(t)* is estimated and cancelled. Here it is assumed that *g(t)* is available in real-time. The sliding surface $\sigma$ in (4) can be selected as

$$\dot{x}_1 = \alpha_1 |x_1|^{(P-1)/_P} sign(x_1) + x_2$$
$$\dot{x}_2 = \alpha_2 |x_1|^{(P-2)/_P} sign(x_1);\ \sigma = x_1 \qquad (5)$$

**Lemma** Let p ≥ 2, $\alpha_1, \alpha_2 > 0$ then the system (5) is finite time stable. The settling time is a continuous function and depends on the initial condition. Also it vanishes at the origin.

The Lemma can be proved by selecting the Lyapunov candidate function as

$$V = \frac{{x_2}^2}{2} + \int_0^{x_1} \alpha_2 |z|^{(P-2)/_P} sign(z)\, dz \qquad (6)$$

and then applying LaSalle theorem [39]. It is also homogeneous with the dilation $dk{:}(x_1,\ x_2) \mapsto (k^p x_1,\ k^{p-1} x_2)$ and the degree of homogeneity is $-1$.

The term *g(t)* is unknown bounded disturbance and the sliding variable $\sigma$ is very sensitive to this disturbance. It is assumed that the terms *g(t)* and *u(t)* are available, $g^{(m-1)}(t)$ *has* a known Lipshitz constant $L$>0 *by* $m$−1 times differentiability of *g(t)*. The *u(t)* is Lebesgue-measurable input control function and $\sigma(t)$ is continuous function defined ∀$t$ >0 i.e. it is understood in the Filippov sense. Then

$$\dot{\sigma} = \dot{V}_{fc} - \dot{V}_r \qquad (7)$$

Putting values $\dot{V}_{fc}$ (see appendix B) [37].

$$\dot{\sigma} = f_1\, \dot{x}_4 + f_2 \dot{x}_5 + f_3 \dot{x}_6 - f_4 \dot{x}_7 - n_s \dot{x}_{11} + f_5 - \dot{V}_r \qquad (8)$$

Now applying $\dot{x}_5$ values and then by simplifying we get

$$\dot{\sigma} = g(t) + b\, U_{P_A} \qquad (9)$$

Where

$$g(t) = f_1\, \dot{x}_4 + f_2\, [-2\xi_1(x_4)x_5 - \xi_2(x_4)I] + f_3 \dot{x}_6 - f_4 \dot{x}_7 - n_s \dot{x}_{11} + f_5 - \dot{V}_r \qquad (10)$$

$$b = 2 f_2\, \xi_1(x_4) \qquad (11)$$

The control law $U_{P_A}$ that would maintain $\dot{\sigma} = 0$, i.e.

$$U_{P_A} = \frac{1}{b}[-g(t) + U_d] \qquad (12)$$

$$U_d = \alpha_1 |\sigma|^{2/_3} sign(\sigma_1) + \alpha_2 \int |\sigma|^{1/_3} sign(\sigma)\, d\tau \qquad (13)$$

Since the function $g(x)$ is differentiable, so it has a Lipshitz constant. As it is very difficult to estimate the exact value of the Lipshitz constant L for $\dot{g}(x) \leq L$ , it is the only parameter for proposed observer, so can be estimated through some hit and trial method. $g(x)$ is estimated using observer with the paramters m=2, $\lambda_0 = 2$, $\lambda_1 = 1.5$, $\lambda_2 = 1.1$, [40].

$$\dot{z}_0 = \nu_0 + b\, U_{P_A}$$
$$\nu_0 = -\lambda_0 L^{1/3} |z_0 - \sigma|^{2/3} sign(z_0 - \sigma) + z_1\ ; \qquad \lambda_0 = 2$$
$$\dot{z}_1 = \nu_1$$
$$\nu_1 = -\lambda_1 L^{1/2} |z_1 - \nu_0|^{1/2} sign(z_1 - \nu_0) + z_2; \quad \lambda_1 = 1.5$$
$$\dot{z}_2 = -\lambda_2 L\, sign(z_2 - \nu_1); \qquad \lambda_2 = 1.1$$
$$\hat{g}(x) = z_1 \qquad (14)$$

If there is no noise at the input, after finite time as the transients die out, we obtain $\hat{g}(x) = g(x)$ in (14). The SSOSM Control Law in terms of hydrogen input at anode $U_{P_A}$ with parameters $p = 3, m = 2$ will become

$$U_{P_A} = \frac{1}{b}\left(\alpha_1 |\sigma|^{2/3} sign(\sigma) + \alpha_2 \int |\sigma|^{1/3} sign(\sigma)\, d\tau + \hat{g}(x)\right) \qquad (15)$$

$$U_{P_A} = \frac{1}{b}\left(U_d + \hat{g}(x)\right) \qquad (16)$$

Which is the SSOSM Control with robust finite time convergent term, $U_d$.

## C. Simulation Results:

The smooth control signal generated by HSSM controller to control input hydrogen pressure is represented in Fig. 11; there is no chattering at all. This result is the main objective of HSSM controller and is better than presented in [37,38].

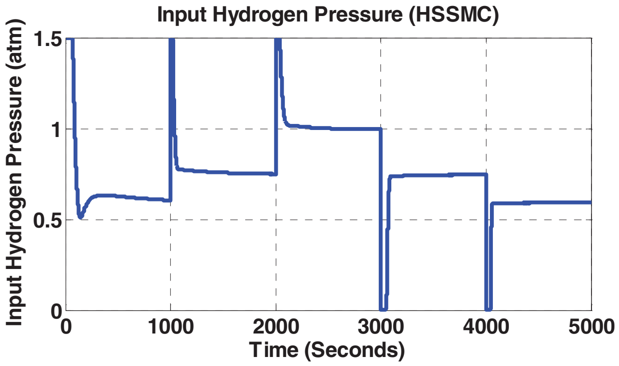

Figure 11. PEMFC Input Hydrogen Pressure HSSMC

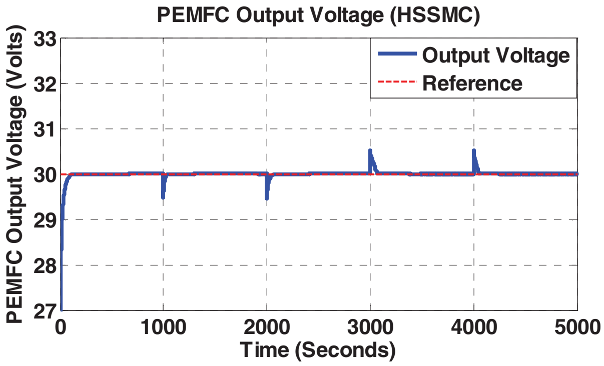

Figure 12. PEMFC Output Voltage HSSMC

The PEM fuel cell output voltage stabilized at 30 volts by HSSM controller is shown in Fig. 12. It can be seen that for two undershoots at 1000 and 2000 seconds the output voltage comes back to the reference value quickly where as in case of two overshoots at 3000 and 4000 seconds the output takes little more time to returns the reference value. The load current increases at 1000 and 2000 whereas it decreases at 3000 and 4000 seconds. When load current increases the fuel cell needs more fuel to maintain the voltage level that surplus amount can be rapidly provided by the controller where as in the case when the load current decreases the high pressure fuel stored in the gas chambers need some time to consume it up.

The sliding surface in case of HSSM controller ideally it remains at zero. The peaks are due to the load current profile given to the system. The Fig. 13 shows the robustness of the controller. The sliding surface leaves the manifold to cater the load disturbance for a few seconds and remains there forever.

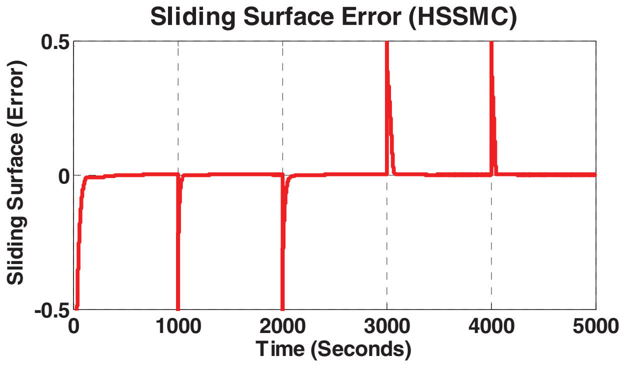

Figure 13. Sliding Surface HSSMC

## Conclusion

A novel chattering free smooth second order sliding mode control (SSOSMC)/HSSMC is studied to tackle the problem of PEM fuel cell system output voltage stabilization problems along with controlling oxygen excess ratio. The oxygen excess ratio is controlled in the inner control loop using PID while the regulation of output voltage is being treated in the outer loop through HSSM control. The control law is designed for the formulated problem and stability analysis is provided. The simulation is carried out on the nonlinear, validated model. Finally, it is shown from the simulation that HSSM controller provides the smooth/ chattering free control which is robust against uncertain disturbances and minimize fuel consumption by showing minimal control efforts. The proposed controller is far better in avoiding chattering and easy for implementation than the previously applied different techniques for the formulated scheme.

*Abstract*—**For the rapid alignment of the ship-borne weapon INS with large initial azimuth attitude error under complex environment disturbances, a nonlinear error propagation model augmented by sensor errors and disturbance sources was proposed. Velocity plus angular rate matching method was applied in the implementation of the alignment. Simulation results show that comparing with the conventional solutions, this method can accomplish the transfer alignment of a mooring ship's weapon INS with large heading error rapidly and accurately. Meanwhile, it has strong adaptability to the sea condition and can improve the precision of the alignment under complex environment disturbances.**

## I. Introduction

Aligning SINS (slave inertial navigation system) of lower accuracy by MINS (master inertial navigation system) is called transfer alignment (TA). TA method can align the SINS with short time and high accuracy. Conventional TA error propagation model based on the hypothesis of small misalignment angle between SINS and MINS is linear; however, there might be large heading error between the frames of the two INSs in ship-borne TA process[1],[2]. Thus, it is necessary to study the methodology of TA with large azimuth misalignment.

In the works [3]and [4], velocity matching was used to execute the TA with large heading misalignment angle of SINS, but the long alignment time cannot meet the operational requirements. In the research [5] , velocity plus angular rate matching TA method estimated attitude errors accurately and rapidly only by virtue of swaying movement caused by sea waves, when the misalignment angles are small. Meanwhile, it can give good estimations of gyro-drifts. However, there are few researches on this matching method under the condition of large azimuth attitude error between SINS and MINS.

There are some special problems for the transfer alignment between the ship-borne weapon INS and the Master INS. On the one hand, it is inappropriate for large warship to execute maneuver in order to accomplish the alignment. On the other hand, ship-borne TA is badly affected by environment disturbance. Based on the above considerations, a new approach of the TA for ship-borne weapon with large azimuth error was studied in this paper. This alignment method used the differences of velocity and angular rates between SINS and MINS as the measurements. Meanwhile, dynamic and static lever arm errors and flexure deformation are augmented to system model of the TA. The alignment method was executed by UKF. Performance of this approach was tested under two typical sea conditions by the simulation.

## II. Error propagation Model of the Transfer Alignment

### A. State-Equations of Transfer Alignment

According to [6], the error propagation equation with the large azimuth misalignment is

$$\dot{\phi} = (I - C_n^{n'})\omega_{in}^n - C_b^{n'}\varepsilon + \eta_\phi \tag{1}$$

In the research [8], lever arm effects were compensated in the velocity error propagation equation, it needs angular acceleration information to calculate compensation item, and however, the angular acceleration cannot be obtained directly. Difference calculation is needed in order to get angular acceleration, but it will bring extra alignment error. Therefore, in this paper, instead of compensating lever-arm effects in velocity error propagation equation, those errors were compensated in the velocity measurement. Thus, the velocity error propagation equation is

$$\delta\dot{v}_s^n = [I-(C_n^{n'})^T]C_b^{n'}f^b - (2\omega_{ie}^n+\omega_{en}^n)\times\delta v_s^n + C_b^{n'}\bigtriangledown^b + \eta_v \tag{2}$$

In (1)and (2), $\phi$ is the attitude misalign vector between SINS′s and MINS′s navigation frames, $\delta v_s^n$ is the velocity error vector of SINS, $\eta_\phi$and $\eta_v$ are the noise vectors of attitude and velocity, $C_n^{n'}$ is the transform matrix from the true navigation frame($n$) to the SINS′s navigation frame($n'$), $C_b^{n'}$is the body-axes-to-navigation direction cosine matrix of SINS. When the azimuth attitude error is large, $C_{n'}^n$ is given by the following form

$$C_{n'}^n = \begin{bmatrix} cos\phi_z & -sin\phi_z & \phi_y cos\phi_z + \phi_x sin\phi_z \\ sin\phi_z & cos\phi_z & \phi_y sin\phi_z - \phi_x cos\phi_z \\ -\phi_y & \phi_x & 1 \end{bmatrix} \tag{3}$$

978-1-4673-1560-9/12/$31.00 ©2012 IEEE

The flexure deformation, which is generated by sea waves, winds and engine vibration, can be approximated by a second-order Markov process [6] [7]

$$\ddot{\theta}_{fi} + 2\beta_i \dot{\theta}_{fi} + \beta_i^2 \theta = \eta_i \quad (i = x, y, z) \tag{4}$$

Where, $\theta = [\theta_x, \theta_y, \theta_z]^T$ is the flexure deformation vector, and its variance is $\sigma = [\sigma_x, \sigma_y, \sigma_z]^T$, $\eta = [\eta_x, \eta_y, \eta_z]^T$ is a white noise process with strength given by the diagonal matrix $Q_n$. $\beta = [\beta_x, \beta_y, \beta_z]^T$ is a constant vector. The relationship between $Q_{ni}$, $\sigma_i$and $\beta_i$ is $Q_{ni} = 4\beta_i^3 \sigma_i^2 \quad (i = x, y, z)$ ,and the correlation time $\tau_i$ of the stochastic process is related with $\beta_i$ by $\beta_i = 2.146/\tau_i \quad (i = x, y, z)$ .

For the time of the TA is short, the random errors can be treated as white noises besides the zero-biases of the gyros and accelerometers. Thus, the models of gyro and accelerometer can be approximated as

$$\varepsilon = \varepsilon_b + \varepsilon_w \tag{5}$$

$$\bigtriangledown = \bigtriangledown_b + \bigtriangledown_w \tag{6}$$

where, $\varepsilon_b$ is constant zero-drift, $\varepsilon_w$ is Gaussian white noise. $\bigtriangledown_b$ is constant zero-bias, $\bigtriangledown_w$ is Gaussian white noise.

The measurement error vector of static lever arm is constant, thus $\delta\dot{r}_{meas}^T = 0$ . According to the investigation [8], since the deformation angle is small, the dynamic lever arm length $(\delta r_f)$, which is caused by the deformation, can be described as $\delta r_f = R\theta_f$, thus

$$\delta\dot{r}_f = R\dot{\theta}_f = R\omega_f \tag{7}$$

where,

$$H = \begin{bmatrix} 0 & z_0 & 0 \\ 0 & 0 & x_0 \\ y_0 & 0 & 0 \end{bmatrix} \tag{8}$$

Comparing with the conventional TA model of large azimuth misalign, in order to estimate those environment disturbances in the alignment process, this augmented model is established.

### *B. Measurement Equations*

The measurements of this TA method are velocity and angular rate differences of of SINS and MINS.

As discussed above, the lever-arm effects should be compensated in the velocity matching measurement, thus

$$\Delta v = v_s^n - v_m^n = \delta v_s^n + v_r^n \tag{9}$$

The compensation for velocity measurement is governed by (10), if the measurement of the lever-arm is accurate

$$v_r^n = C_m^n(\omega_{im}^m \times r_0^m) + C_m^n \dot{r}_0^m \tag{10}$$

where, $r_0^m$ is the deterministic lever-arm in the body-frame of MINS, which can be measured beforehand, and $\dot{r}_0^m = 0$ in this situation,$\times$ stands for the skew matrix of the vector.

However, there are some uncertain errors, which cannot be measured accurately. These errors are the static lever-arm measurement error $(\delta r_{meas})$ and the dynamic lever-arm error $(\delta r_f)$ caused by deformation. Thus, the real lever-arm is as following

$$r = r_0 + \delta r_{meas} + \delta r_f \tag{11}$$

Accordingly, the compensation item of the velocity measurement is

$$v_r^n = C_m^n[\omega_{im}^m \times (r_0^m + \delta r_{meas}^m + \delta r_f^m)] + C_m^n \delta\dot{r}_f \tag{12}$$

where, $\omega_{im}^m \times$ is the skew matrix of vector $\omega_{im}^m$.

After compensating the deterministic lever-arm effect by (10), the velocity matching measurement is still affected by $\delta r_{meas}$ and $\delta r_f$, and it is governed by (13)

$$\begin{aligned} \Delta v &= \delta v_s^n + C_m^n[\omega_{im}^m \times (\delta r_{meas}^m + \delta r_f^m)] + C_m^n \delta\dot{r}_f \\ &= \delta v_s^n + C_m^n[\omega_{im}^m \times (\delta r_{meas}^m + \delta r_f^m)] + C_m^n R\omega_f \end{aligned} \tag{13}$$

The angular rate measurement is the difference of angular rates of SINS and MINS in each navigation frame, therefore

$$\Delta\omega = \omega_{ibs}^{n'} - \omega_{ibm}^n = C_{bs}^{n'} \omega_{ibs}^{bs} - C_{bm}^n \omega_{ibm}^{bm} \tag{14}$$

where, $bm$ and $bs$ are the body frames of MINS and SINS respectively. $\omega_{ibs}^{bs}$ and $\omega_{ibm}^{bm}$are the outputs of angular rates of SINS and MINS respectively. The relationship of $\omega_{ibs}^{bs}$ and $\omega_{ibm}^{bm}$ is

$$\omega_{ibs}^{bs} = C_{bm}^{bs}(\omega_{ibm}^{bm} + \omega_f^{bm}) + \varepsilon \tag{15}$$

Substituting (15) into (14), then the

$$\begin{aligned} \Delta\omega &= C_{bm}^{n'} \omega_{ibm}^{bm} + C_{bs}^{n'} \omega_f^{bs} + C_{bs}^{n'} \varepsilon - C_{bm}^n \omega_{ibm}^{bm} \\ &= C_n^{n'} \omega_{ibm}^n - \omega_{ibm}^n + C_{bs}^{n'} \omega_f^{bs} + C_{bs}^{n'} \varepsilon \\ &= (C_n^{n'} - I)\omega_{ibm}^n + C_{bs}^{n'} \omega_f^{bs} + C_{bs}^{n'} \varepsilon \end{aligned} \tag{16}$$

Comparing with the traditional TA method, the circumstance disturbances are augmented to this TA model, and these errors can also be reflected in the measurement equations.

## III. Simulation verification of the TA method

Augmenting the deformation and lever-arm errors to the TA model, the states of the TA filter are as follows

$$X = \begin{bmatrix} \phi^T & \delta v^T & \varepsilon^T & \bigtriangledown^T & \theta_f^T & \omega_f^T & \delta r_{meas}^T & \delta r_f^T \end{bmatrix}^T \tag{17}$$

Summarizing the TA filter model, the state vector is defined as (17), and the corresponding state equation consists of the attitude error (1), velocity error (2), the disturbances (4) and (7) ,and constant zero-bias of IMU (5)(6).

Adding velocity measurement noise and angular rate measurement noise to (13) and (16), the measurement equations of this TA filter are

$$\begin{cases} Z_{\Delta v} = \Delta v + \lambda_{\Delta v} \\ Z_{\Delta\omega} = \Delta\omega + \lambda_{\Delta\omega} \end{cases} \tag{18}$$

where, $\lambda_{\Delta v}$ and $\lambda_{\Delta\omega}$ are the measurement noises of velocity matching and angular rate matching respectively.

The implementation of this TA method is by UKF [4], [10].

The ship is mooring in the TA process. Under the waves excitation, the ship sways around the pitch axis, the roll axis

TABLE I
PARAMETER SETTINGS OF FLEXURE DEFORMATION

| Sea condition | Parameter | | | |
|---|---|---|---|---|
| | Variable | Roll | Pitch | Yaw |
| Medium sea | Amplitude | $1'$ | $15'$ | $3'$ |
| | Correlation time | 60s | 60s | 60s |
| Peaceful sea | Amplitude | $1'$ | $6'$ | $2'$ |
| | Correlation time | 60s | 60s | 60s |

TABLE II
ERRORS OF THE SINSS IMUS

| Sensor error | Accelerometer | | Gyro | |
|---|---|---|---|---|
| | Constant zero-bias | Random walk coefficient | Constant zero-drift | Random walk coefficient |
| Degree1 | 100 $\mu$g | 10$\mu$g/$\sqrt{h}$ | 0.01°/h | 0.001°/$\sqrt{h}$ |
| Degree2 | 400$\mu$g | 40 $\mu$g/$\sqrt{h}$ | 1°/h | 0.05°/$\sqrt{h}$ |

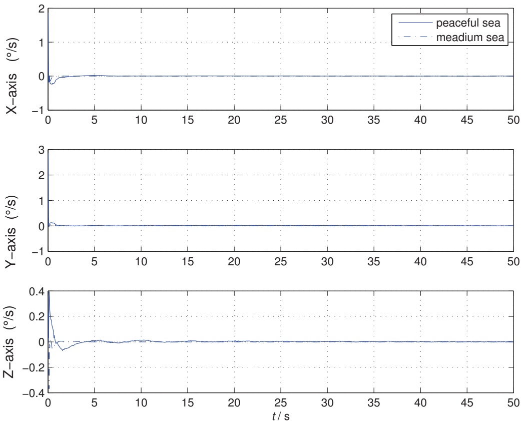

Fig. 1. Estimation bias of flexure deformation angular rate.

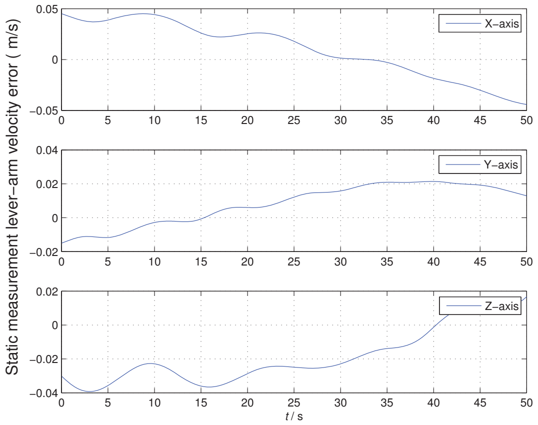

Fig. 2. Velocity error caused by the static lever-arm measurement error.

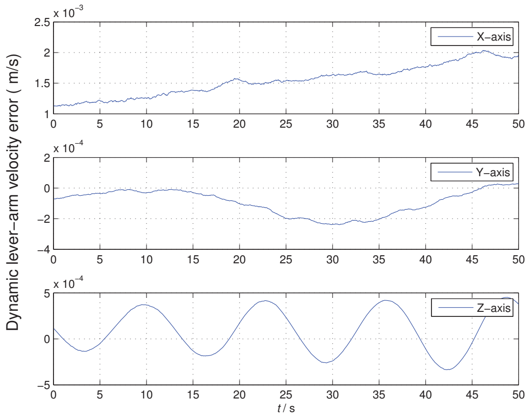

Fig. 3. Velocity error caused by the dynamic lever-arm error.

and the heading axis separately for sinusoidal motion. The model is given as follows

$$\begin{cases} \psi = \psi_m \sin(\omega_p t + \varphi_p) \\ \gamma = \gamma_m \sin(\omega_r t + \varphi_r) \\ H = H_m \sin(\omega_h t + \varphi_h) \end{cases} \tag{19}$$

where, $\psi_m$ ,$\gamma_m$ and $H_m$ are the amplitudes of the sway. $\omega_i = 2\pi/T_i(i = p, r, h)$ ,and $T_i$ is the period of sways. $\varphi_i(i = p, r, h)$ is the initial phase, and $\varphi_i(t)$ is a random value in $(-2\pi, 2\pi)$. Parameters of the above model are determined by the sea condition, two sea conditions are studied in this paper, one is medium sea condition, and another is peaceful sea condition, the parameters of these two conditions are

For medium sea condition,
$\psi_m = 2.5°$ ,$\gamma_m = 12°$ ,$H_m = 4°$ ;
$T_p = 8s$,$T_r = 13s$ ,$T_h = 40s$ .
For peaceful sea condition,
$\psi_m = 0.5°$ ,$\gamma_m = 2°$ ,$H_m = 2°$ ;
$T_p = 5s$,$T_r = 10s$ ,$T_h = 60s$

The parameter settings of the flexure deformation are shown in table I. The TA method is also tested by two different accuracies (see table II) of the SINSs IMUs

This TA filter can estimate flexure deformation angular rate accurately, the results are shown in Figure 1.

The disturbance of the lever-arm effect becomes bigger as the strength of the ships sway increases. Thus, in the following simulation, the influence of the lever-arm error is analyzed in the medium sea condition. where, let $\delta r^m_{meas} = [0.5\text{m}, 0.5\text{m}, 0.5\text{m}]^T$ . The velocity errors caused by $\delta r_{meas}$ and $\delta r_f$ are shown in Figure2 and Figure3.

From Figure2 to Figure5, we can see that the velocity error caused by $\delta r_{meas}$ and $\delta r_f$ influenced the velocity measurement in certain degree, and this disturbance is even more harmful to SINS of high sensor accuracy (such as a shipboard aircraft). Thus, in order to get useful velocity measurement for the TA filter, these errors must be compensated. This TA method can estimate $\delta r_{meas}$ and $\delta r_f$ accurately, the estimation errors of them are shown in Figure6 and Figure7.

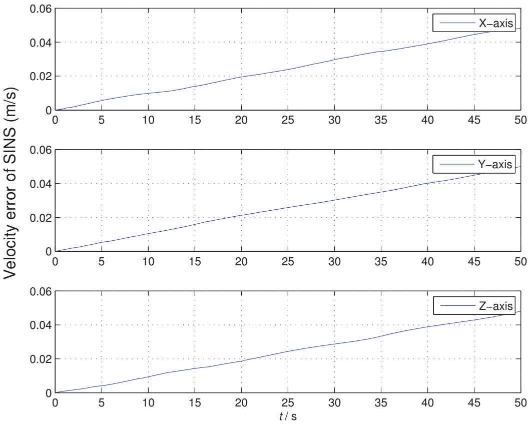

Fig. 4. Velocity error of SINS with IMU error degree 1.

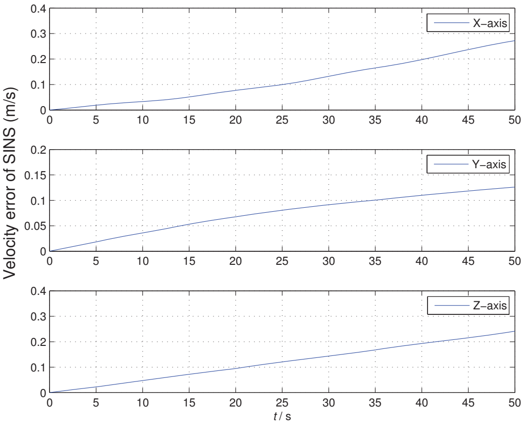

Fig. 5. Velocity error of SINS with IMU error degree 2.

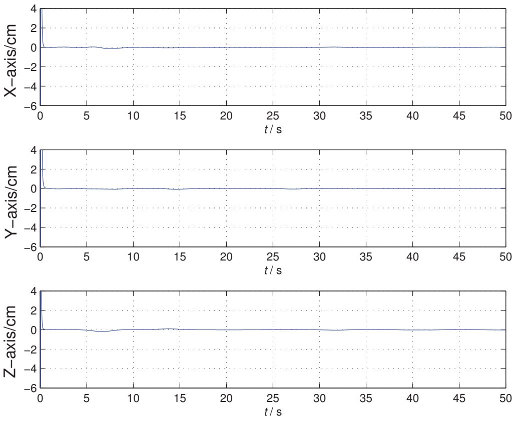

Fig. 6. Estimation bias of the static lever-arm measurement error.

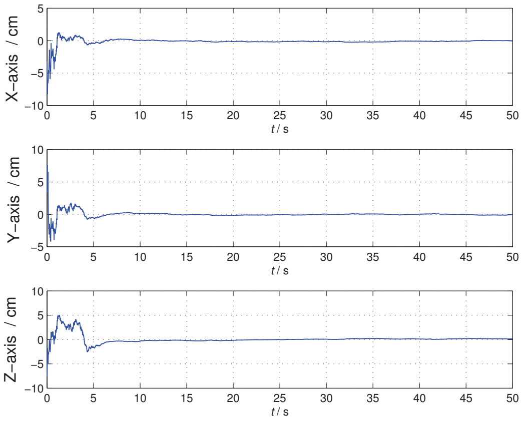

Fig. 7. Estimation bias of the dynamic lever-arm error.

TABLE III
TA RESULTS OF DIFFERENT COMPENSATION SITUATIONS

| Estimation error | Different compensation situations | | | |
|---|---|---|---|---|
| | Situation1 | Situation2 | Situation3 | Situation4 |
| $\phi_x$ | $9.9701'$ | $9.4511'$ | $5.1821'$ | $4.0645'$ |
| $\phi_y$ | $16.5467'$ | $15.9928'$ | $4.3780'$ | $3.9019'$ |
| $\phi_z$ | $13.7641'$ | $12.7643'$ | $6.4335'$ | $5.0075'$ |

The static lever-arm measurement error of a shipboard aircraft can be more indeterminate, thus, let $\delta r^m_{meas} = [1.5\text{m}, 1.5\text{m}, 1.5\text{m}]^T$ in the following simulation. Table III shows the TA results of partial or all disturbance compensations. In situation 1, there are no compensations of both lever-arm error and deformation. In situation 2, there is only lever-arm error compensation. In situation 3, there is only deformation compensation. In situation 4, all the disturbances are compensated by the method of this paper.

The simulation results shows that both flexure deformation and lever-arm error affect the accuracy of the TA in some degree, see Table III, whereas the TA method in this paper can compensate all these disturbances very well, and the alignment accuracy can be improved a lot. From the alignment results in the four situations of different sea condition and sensor error , as shown in Figure8 through Figure11, we can get that this TA method has strong adaptability to the sea condition, and the degree of sensor error does not affect the TA results too much (see table IV).

The above results are acquired in the situation that the measurement noises of actual value and the TA filter are same.

TABLE IV
ESTIMATION BIASES OF MISALIGNMENT ANGLES OF THIS TA METHOD

| Sea condition | Sensor error degree | $\phi_x$ | $\phi_y$ | $\phi_z$ |
|---|---|---|---|---|
| Medium sea | Degree 1 | $4.0645'$ | $3.9019'$ | $5.0075'$ |
| | Degree 2 | $4.5735'$ | $4.3017'$ | $5.5971'$ |
| Peaceful sea | Degree 1 | $4.8917'$ | $4.0133'$ | $5.4335'$ |
| | Degree 2 | $5.0103'$ | $4.3855'$ | $5.8011'$ |

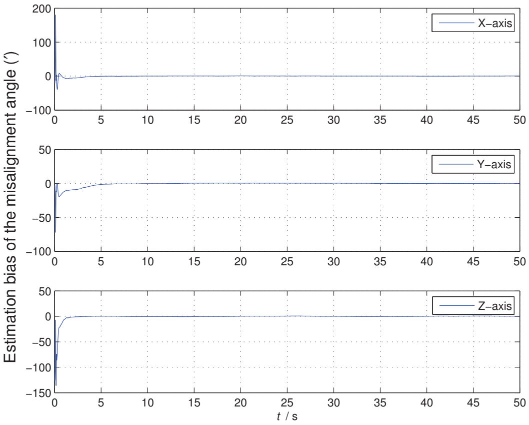

Fig. 8. Estimation bias of the misalignment angle, in the condition of medium sea and sensor error degree 1.

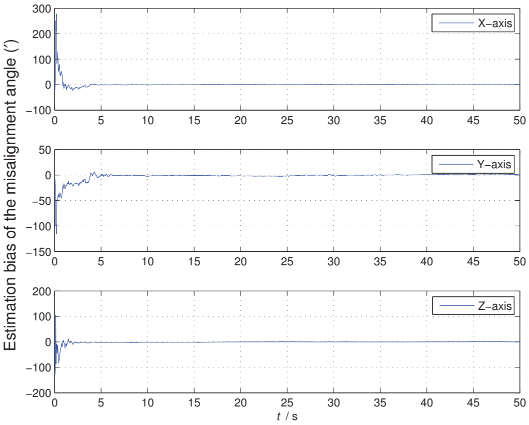

Fig. 9. Estimation bias of the misalignment angle, in the condition of medium sea and sensor error degree2 .

From(16), we can see that deformation angular rate is a main disturbance of angular rate matching measurement. In the TA method of this paper, the flexure deformation disturbances are augmented to the states of the TA filter, the measurement disturbance could be compensated to some extent in the process of alignment filtering. Thus, the actual measurement noise will just change in a small range. Assuming that the actual measurement noise is two times larger than the TA filter's. The comparison simulations are carried out in the condition of peaceful sea and sensor error degree 1, and the results are shown in Figure 12. The estimation bias of the misalignment angle is $\delta\phi = [5.5011', 4.7566', 5.6179']^T$.

The simulation results show that the bigger actual measurement noise can cause lower accuracy of the misalignment angle estimation. Meanwhile, the research [11] has shown that the adaptive Kalman filter could be one solution of this problem.

Besides, time-delay is another influencing factor of TA.

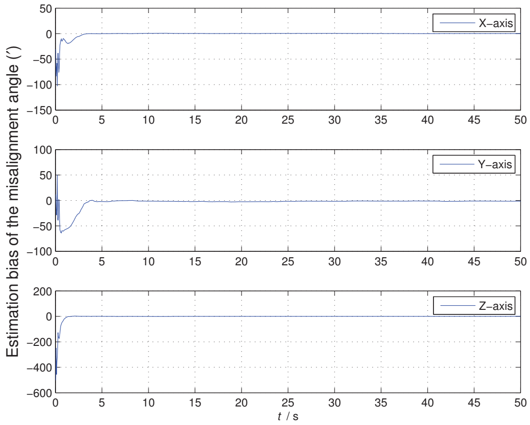

Fig. 10. Estimation bias of the misalignment angle, in the condition of peaceful sea and sensor error degree 1.

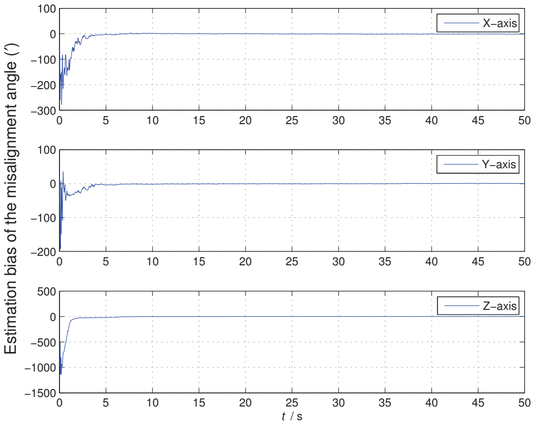

Fig. 11. Estimation bias of the misalignment angle, in the condition of peaceful sea and sensor error degree 2.

According to the research [12] , time delay may cause some misalignment between the MINS and SINS, which can reduce the accuracy of the TA. Recent research [12] has shown that the fire control computer of the MINS can give the time-delay information to the SINS, then the data can be processed by Kalman filtering and the time origin is unified to the moment corresponding to the MINS data. Therefore, the time-delay barely affects the TA process in this situation.

## IV. Conclusion

This transfer alignment method is for the purpose of reducing alignment errors induced by the disturbances and aligning the weapon INS with large azimuth attitude error on a mooring ship. The method has been established through the disturbances state augmentation and velocity plus angular rate matching, and via qualitative explanations and interpreting computer simulation results, it turns out to be that comparing with the conventional TA method the present one is more

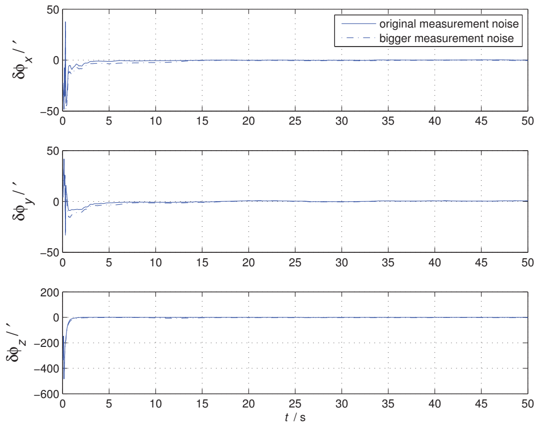

Fig. 12. Comparison of estimation bias of the misalignment angle under two different measurement noise situations

suitable for weapon INS with large azimuth attitude error of a mooring ship under complex environment disturbances.

A related further research of TA with large azimuth attitude error should develop an adaptive state estimation method in face of uncertain measurement noise and an error compensation scheme based on uncertain time-delay.

# Study on The Method of Multi-agent Generation Algorithm within Special Artificial Society Scene

Zongchen Fan, Wei Duan, Bin Chen, Yuanzheng Ge, Xiaogang Qiu

School of Mechatronics Engineering and Automation
National University of Defense Technology
Changsha, Hunan
andy_van1@sohu.com

*Abstract*—**Multi-agent generation within a special scene is a basic problem for the research on artificial society. In the context of public health emergency, the multi-agent model of an artificial campus is built; based on the deep analysis of the problem, we consider that a special scene in artificial society is approximate to a polygon determined by some key points (border points). Therefore the problem of multi-agent generation is converted to inner-point generation in the polygon. The grid-based method is proposed to divide the scene polygon reasonably consistent to the density. The filtering mechanism of grids generated is proposed. Finally, the experiment shows that the method could be used to generate some agents with some properties in a special scene randomly, and has certain reference value.**

***Keywords-artificial society; scene; grid method; infinite element***

## I. Introduction

The problem of modeling highly integrated and complex artificial society involves many aspects of natural and artificial systems, social organizations, individual psychology and behavior, with a variety of uncertainties and opposability [1]. The wide application of the computing technology and the maturity of numerical method have make it true to research the dynamics of social system in use of simulation. In early 1990s，the Land Corporation proposed the concept of artificial society, and from that on, artificial society has begun to spring up. The core method of artificial society is based on the modeling and analysis of the Agents. Its basic idea is described as following: human society is a complex system which contains a lot of individuals, and the individuals could be modeled in the computer (that is the software agent); the agents should follow certain rules of interaction; the social or group phenomena emerged by observing the whole behavior of the agents, and the model of the complex social system could be built to study information technology impact on the society, politics and culture [1, 2, 3]. The simulation of artificial society based on multi-agents modeling has become an effective solution to solve complex social systems.

In recent years, various unconventional emergencies have occurred one after another in China, and emergency management has become the major challenge to the social management. The method and technique of computer simulation used to build the scenario of the incident's happening, development, transformation and evolution has been considered the most important way to solve "scene-response" problem of unconventional emergency management. The research has been carried out abroad for some years. Arizona State University in the United States built a 8000 square feet named Decision Theater for decision support in the emergency scene in 2005. In 2007 and 2008, the U.S. Department of Homeland Security implemented the Golden Guardian for the terrorist attack and earthquake in California. The key component is the Exercise Control System to support scenario generation, learning and training, tissue remodeling, and so on [4, 5].

The scene could be considered as the environment and condition where the agents are located in artificial society, while usually the agents are constrained to act in a special area. The paper mainly studies the random generation of agents with some particular characteristics within the special scene of artificial society, and the groundwork is built for the next research.

## II. Multi-Agent Model

Based on the complex network modeling technology and the real system information acquisition technology, multi-agent system could be introduced to describe the groups and individuals in human society, which could provide the good technology ground for recurring the complexity of the social system, and approaching the social context of unconventional emergencies [6]. While social system is the complex system which contains a large number of intelligent agents, the method of agent-based modeling and simulation is feasible to describe the individual or group behavior, and analyze the social structure evolution and group behavior law with the interaction between agents. Multi-agent system is composed of many agents interacting with each other. There are also some interactions between agents and environment. Generally, each individual agent could make decision independently, and has the ability of adaptive, learning and cognition [7, 10].

The paper mainly focuses on the spread of infectious diseases within a campus, and builds the artificial campus in the context of unconventional public health emergency. The population agent in artificial society should be set the basic demographic attribute to establish the population statistics model within a specified scene in use of the population census statistics. The agents with different demographic attributes

978-1-4673-1560-9/12/$31.00 ©2012 IEEE

and different spatial distribution could be generated automatically in geography environment. Agent modules in a campus include population statistics model, agent behavior model, disease-related model, the social relationship model, and agent interaction model [8-10].

$$Agent_{individual}:\left\{\begin{array}{l} demography\ model(t) \\ activity\ model(t) \\ disease\ referred\ model(t) \\ social\ relationship\ model\ (t) \\ communication\ model(t) \end{array}\right\}$$

The agent's population census statistics can be described from two aspects. One is public population census attributes, owned by any agent in any application area, such as ID, sex, age, role, and so on ; the other is domain-related population census attribute, for example, in public health event, including the immunity ability, symptoms, duration of symptoms, spread probability, and so on.

The agents in artificial society can be categorized according to the role of population census. A class of agent represents a kind of entity in real world. Based on the agent model with public population census attributes, the special attributes and behavior rules can be added newly. For example, except for the basic attributes (ID, sex, age) for the student agent, the special attributes (grade, professional, class) and related behaviors (entertainment, community activities, sports) should be added. A common agent could be described as shown in fig.1.

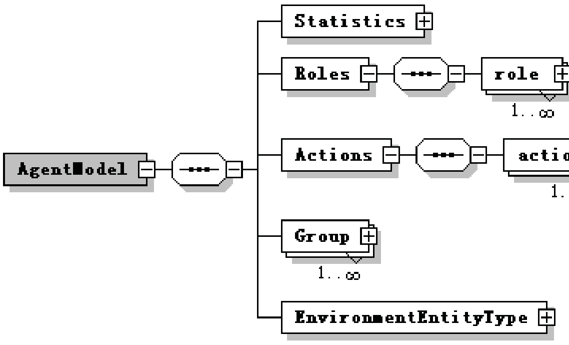

Figure 1. Agent model

## III. Boundary of special scene

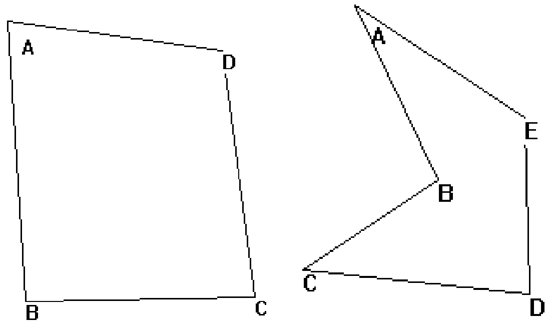
### A. Setting the Boundary

The scene is the place where the agents act, and has its own boundary and constraint. The agents always act within a certain area, and execute some related activities.

There are some criteria to justify the algorithm. The agents must be generated inside the scene, and the distribution of different agents should be consistent with the density of different agent in the scene. In order to determine the scene boundary, the coordinate of some key points which reflect the boundary shape should be given, and the scene can be generated based on the points. Especially for the complex shape, it's feasible to depict the scene in use of polygon approximation, and in error permission the complex shape between two points can be approximated by a straight line segment [13]. For the sake of simplicity, the scenes generated in the paper are closed polygon shape.

Given a point array $\{(x_1,y_1),(x_2,y_2),\cdots,(x_n,y_n)\}$ , the algorithm generating n edges shape is described as following: firstly, the index counter should be defined, and record the number of connected nodes. The initial state of the index counter is Zero. Secondly, the point $P(x_p,y_p)$ selected from n key points ($1\le p\le n$) is regarded as the start point, and the index counter should be added by 1. Then the adjacent points should be connected in sequence. Whenever a point is connected, the index counter should be added by 1. In the step the closure of polygon should be judged. If the value of the index counter is greater than n, and the point returns to the start point, the shape could be considered to be closed. So the lines between adjacent points as the sides of polygon are regarded to be the boundary of the scene.

Usually, the expressed way of the polygon in the computer is to sort the order of adjacent vertices arranged in an array. When shown the vertices can be connected by a straight line according to the store order. Geometry shape is ultimately described by the polygon.



(a) (b)

Figure 2. Polygon generated

### B. Judging the Relationship between Points and Scene

After the boundary of the scene generated, the activity range is determined in artificial society. It's important to make sure that agent should act in a special area, and can't exceed any boundary. The section mainly proposes the ray method to judge the relationship between the points and scene through refining an agent to be a single point in geography space.

At present, the ray method is the most widely used to judge the space relationship between points and polygon in engineering area [15, 16]. It's basic principle is described as following: Given a judging point P, the ray L is drawn along the direction of the polygon from the point P(Generally the ray parallels x axis or y axis); then the number of the intersection points is calculated. The relationship could be judged according to the parity of the number. That is the "odd number internal, even number external" rule. However, the rule isn't always suitable for any condition. There are still some special conditions to deal with.

(1)If the ray and a polygon vertex intersects, and two sides of the vertex lie in both sides of the ray L, the number of the intersection points is just one;

(2)If the ray and a polygon vertex intersects, and two sides of the vertex lie in same sides of the ray L, the number of the intersection points is Zero;

(3)If the ray L comes across two adjacent vertexes in succession (It means that the ray L superposes a side of the polygon), the two vertexes could be considered an intersection point. According to the computing method described in condition (1)(2), if the two fore-and-aft vertexes of the intersection point lie in different sides of the ray L, the intersection point should be regarded one point added to the number of the intersection point; otherwise, it can't be computed.

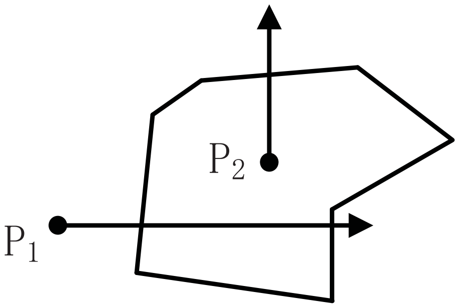


Figure 3. Ray method

The ray could always come through the polygon, because the polygon is bounded. Based on the ray method, the algorithm process could be described as following:

(1)Given the start point $P(x_p, y_p)$, and the polygon formed by a point array $\{(x_1, y_1), (x_2, y_2), \cdots, (x_n, y_n)\}$;

(2)The ray $y = y_p, x \in (x_p, \infty)$ paralleling x axis is drawn from the start point $P(x_p, y_p)$;

(3)Each side $S_i((x_i, y_i), (x_{i+1}, y_{i+1})), i \in [0, n)$ of the polygon is obtained circularly, and there should be some needs to judge whether each side parallels x axis. If paralleling x axis, enter into the next step; otherwise, continue to cycle;

(4)Priority is to judge whether the point $P(x_p, y_p)$ lies on a side of the polygon. If it is, it's thought that the point lies in the polygon and return true, otherwise enter into the next step;

(5)Judge whether the ray $y = y_p$ and the vertex of the polygon intersect. If it is, the position relationship among the ray and the two sides of the vertex can be judged by comparing the abscissa of the vertex with $P(x_p, y_p)$, and if the position lies in different sides, the intersection point counter should be added by 1, otherwise the counter can't be changed; if not, enter into the next step;

(6)Judge whether the ray $y = y_p$ and a side of the polygon overlap. If it is, it could be considered an intersection point. If the adjacent vertexes of the ersatz point lie in the different sides of the ray, the ersatz point can be regarded as a intersection point added to the counter, otherwise the counter unchanged. If not, enter into the next step;

(7)Judge the ray and a side of the polygon intersect. If it is, the intersection point counter should be added by 1; otherwise return to the third step;

(8)Judge the overall number of the intersection points. If the number is odd number, it means the point P lies in the polygon and return true; if even number, it means the point P lies outside the polygon and return false.

## IV. GRID METHOD

Obviously, it's very important to generate some inner points within the scene automatically and randomly. As described above, the auto generation of the inner points within a scene is transformed into the auto generation of the inner points within a polygon. Recently the generation technology of the inner points within a polygon has been developed, such as the approaches based on triangle and MBR [11, 12]. These approaches have made good attempts to solve the problem of inner point generation and received ideal effects. However, the algorithm process may be so trivial and complex that too many computing resources are consumed. We proposed and introduced grid method to make sure that individual agents be ergodic and diversiform, but also not increase the scale of the inner points blindly.

### *A. Grid Density*

The basic idea of grid method is described as follows: according to the boundary of the scene polygon (for example, the value range in x axis or y axis), the scene polygon is divided into many interzone boundaries. All the interzone boundaries are intersected to form many small quadrilateral grids. The intersection points in the quadrilateral grids are the point in search space, as shown in fig. 4. When the initial points are generated, individuals can be full of the whole search space.

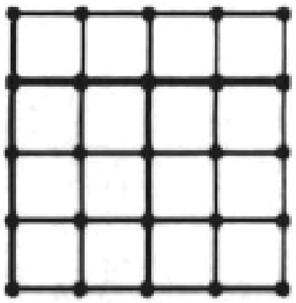

Figure 4. Grid method

In artificial society scene different area might have different population distribution density. There are some concentrated and collective phenomena in real world. It must require that the density of the grid should be considered when the scene is divided.

For the algorithms of quadrangle grids, the most representative is geometric decomposition method. Within it the two best methods are Looping and Paving, while it's hard for the two methods to control the grid density. In order to reflect the density differences among the grids, it's required that the density control should integrate with geometric decomposition.

The density of the grid can be defined as the reciprocal of the grid element length from the view point of mathematics. We adapted Laplace equation to express grid density distribution function within artificial society scene. Grid density distribution should be continuous in the area divided. It could ensure that the grid elements generated based on the grid density have the property of catholicity and universality [13, 14]. Given the grid density $U(x,y)$, the Laplace equation of the grid density distribution function can be described as following:

$$\frac{\partial^2 U}{\partial x^2}+\frac{\partial^2 U}{\partial y^2}=0 \qquad (\text{in } \Omega) \qquad (1)$$

Where $\Omega$ means the area of the scene.

The boundary condition of Eq. (1) is expressed as:

$$\frac{\partial U}{\partial n}=0 \qquad (\text{on } \Gamma) \qquad (2)$$

Where Γ is the boundary of the scene; n is normal direction of the boundary Γ.

Numerical solution of Laplace method can be attained in use of the finite element method [14]. In order to attain the grid density of certain area, the area should be divided into discrete computing elements. As shown in fig.5, the scene is a hexagon area. Based on the minimum rectangle carving, the elements outside the scene are removed, and the scene area is divided into the computing elements.

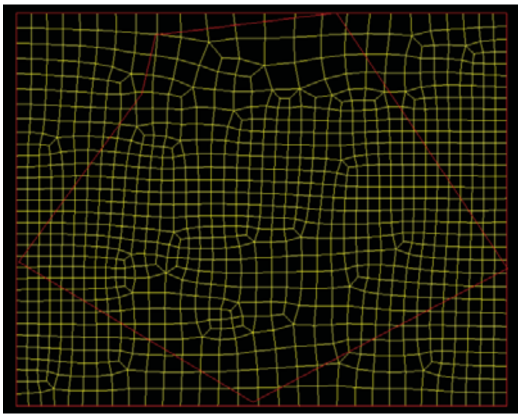

Figure 5. Scene division

The density of each point within grid elements is solved by the interpolation of the density of grid's four vertexes. The shape functions of the four vertexes are described as [14]:

$$\begin{cases} q_1=(1-\xi)(1-\eta)/4 \\ q_2=(1+\xi)(1-\eta)/4 \\ q_3=(1+\xi)(1+\eta)/4 \\ q_4=(1-\xi)(1+\eta)/4 \end{cases} \qquad (3)$$

The density of any point can be expressed as:

$$u(\xi,\eta)=\sum_{i=1}^{4} q_i(\xi,\eta)u_i \qquad (4)$$

Where $\xi,\eta$ are normalized coordinates of elements; $u_i$ is the density value of ith node.

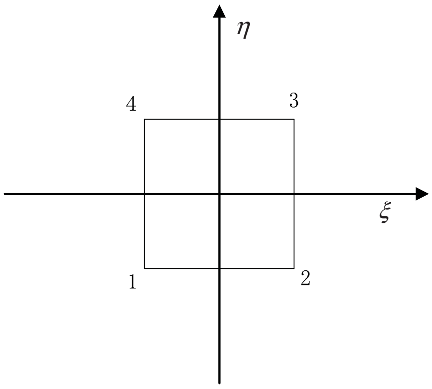

Figure 6. Grid element

Under the known boundary conditions, Eq. (1, 2, 3, 4) are united to solve the density of elements. In fact, the boundary condition of density is equal to determining the density value of the boundary points. The density value of the boundary points can be attained according the curvature. Because the area of the scene is expressed by diagnostic polygon, the length of each side in diagnostic polygon can roughly reflect the curvature of the boundary [13,14].

The division of the grid would need to consider the human activity scale, and the number of the grids divided could be given ahead of time. According to the grid density distribution, the nodes are generated in the boundary. The nodes lie in the sides of diagnostic polygon, generated between two key points. Then these nodes are numbered sequently according to the order. There need to be two steps to complete the process: the first is computing the number of the nodes; the second is determining the location of the nodes.

### B. *Computing the Number of Node*

In order to compute the number of the nodes generated, the integral for the density should be made along two key points, shown as:

$$\int_L u(s)ds = R \cong N-1 \qquad (5)$$

Where N is the overall number of the nodes including two vertexes; L is the connected line between two vertexes; u(s) is the boundary density.

In actual numerical computing, Eq. (5) could be computed according to the following method: the line L can be divided into some same line segment. The density in the middle of the small line segment is regarded as the mean density. Product by multiplying the mean density and the length of the line segment sums into the approximate integral result R. As a real number, the integral result R should be rounded up to the nearest integer N-1. In addition, the overall number of the boundary nodes must be an even number. So to meet the demand, there need to be adjust N. As the result of round, there must be some errors between the grid unit number and setting value.

### C. Determining the Location of Nodes

The finite element iteration technique is used to determining the location of the nodes. Except for the beginning and end nodes, the others are unknown. The location of the nodes(relative to the start point of the length) can be regarded as a dimension variable and the variable should meet certain equation:

$$u(s)ds = Ad\varepsilon = C \qquad (6)$$

Where $u(s)$ is the boundary density function; $d\varepsilon$ is the derivative in computing space (the nodes meet the even distribution in computing space); A is the proportion constant; C is the constant.

The Eq. (6) could be transformed into two-order derivative equation, shown as:

$$\frac{d}{dx}\left[u(s)\frac{ds}{d\varepsilon}\right]=0 \qquad (7)$$

In Eq. (7), the numerical value could be solved in use of emergence element iteration technique. The computing space is divided into N-1 units. Through the unit analysis, the unit stiff equation could be described as:

$$u[\tfrac{s_i+s_{i+1}}{2}]\begin{bmatrix}1 & -1\\ -1 & 1\end{bmatrix}\begin{bmatrix}s_i\\ s_{i+1}\end{bmatrix}=\begin{bmatrix}0\\ 0\end{bmatrix} \qquad (8)$$

Where $s_i$ means the location of the ith node.

The whole stiff equation can be attained by fitting all the unit stiff equations together. The location of the first node is set $s_1 = 0$, and the location of the Nth node is set $s_N = L$ (the length between two key points). The others are assumed to meet the even distribution. The location of each node could be attained by solving the whole stiff equation iteratively.

### D. Generating Randomly

In the paper we use middle-square method to generate the stochastic number. The square method firstly starts from some initial seeds. Based on the algorithm of the square method, false stochastic array could be acquired. After generating false stochastic number, $R_{new}$ is defined according to the number of elements selected in the scene, described as follows:

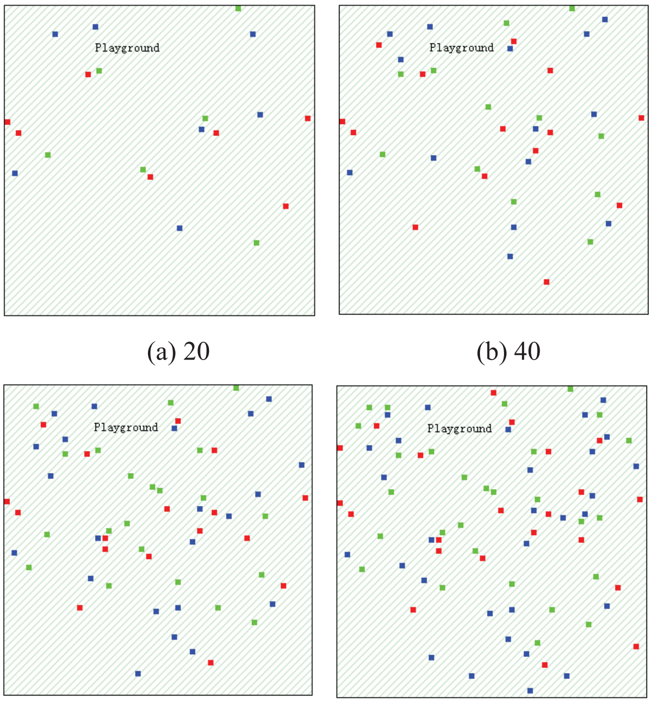
$$R_{new} = rand()/(N-1) \qquad (9)$$

The points in the grids can be indexed from the selected grids. The whole process is random, done completely by computer.

## V. Experiment

The experiment has implemented the auto generation of student agents within the playground artificial campus in the context of public health event. The playground boundary is formed by some key points known firstly. According to the daily statistical data, the personnal distribution is set reasonably.

For simple, the playground is regular rectangle, and the playground scene is divided uniformly. Here, 20, 40, 80 and 100 agents could be generated in the playground respectively given ε=σ=4, as shown in fig. 7. The red point, blue point, and green point represent three kinds of students respectively. Through computing, at the first time the number of the grids selected is 7715. After further selected, the final number of grids is decreased to 7056. The integer introduced in the process of computing the grid number results in the number reduced. Meanwhile the integer leads to error.



(a) 20

(b) 40

(c) 60

(d) 80

Figure 7. Playground Scene

As shown in fig.7, all the agents are almost generated in the playground, and there could be different density in the different district. The simulation has justified the algorithm effectively.

## VI. CONCLUSION

In the paper, we proposed a grid method, fully considered different distribution density within the actual scene, and adapted a division way to reflect agent's distribution. The experiment result showed it don't only generated agents randomly, but also ensured that the agents be ergodic and real. However, we just discussed the auto generation of multi-agents within artificial society scene from the view of 2D, and made some simplification in the process of generation. It's unavoidable that there are still some errors and infects to improve. With the development and maturity of computer and simulation technology, the future construction and implement of the artificial society must face to a wide prospect.

## ACKNOWLEDGMENT

Isfahan, Iran, (E-mail address: majd.najafi@ec.iut.ac.ir, sheikh@cc.iut.ac.ir).

**Department of Electrical Engineering, Najafabad Branch, Islamic Azad University
Najafabad, Iran, (E-mail address: hoseinia@cc.iut.ac.ir).

*Abstract*—**This paper presents a method to stabilize uncertain dead time system based on new robust state predictor. The proposed predictor consists of a state delayed observer. Controller gain and predictor parameters are calculated by solving a nonlinear matrix inequality. More importantly, this method is extended to dead time system with a long time delay or significant uncertainty using sequential sub-predictors (SSP). This predictor composed of collection of sub predictors that each of them predicts the state for a small part of a long time delay. The number of predictors can increase attending the unstability, delay value or uncertainty where the stability condition is satisfied. Examples illustrate the capability of this method.**

***Keywords- Dead time systems, Robust Sequential sub-predictor, Robust control.***

## I. Introduction

Prediction of states or output plays a fundamental role in the control of dead time systems. This is because of delay in input impedes of stabilizing closed loop system via classical controller. To overcome this challenge, many efforts are devoted on presenting a dead time compensator (DTC) or predictor.

The famous model based predictor was presented by Smith [1] in 1957 for stable systems. Smith predictor is then modified for unstable system by Watanabe [2] (MSP) and for mixed unstable and stable systems (USP) in [3]. Moreover, [4] and [5] are applied it for stable systems with an integrator and long time delay. However, MSP may lead to unstable pole-zero cancelation for unstable systems. Therefore good approximate of distributed delay term in MSP is unavoidable to achieve the stability [6]. In addition, MSP is very sensitive to parameters and delay uncertainty. In recent years, some researchers try to improve the robustness of this method [6-12]. Also there exist a few examples that used this predictor for $H_\infty$ control of dead time systems [13-15].

Another family of predictor is classified as Finite-Spectrum Assignment [16] (FSA). The main idea of some state predictor like as Artstein reduction model [17] is much closed to FSA. [18] has been proposed a different version of FSA attending the pole-assignment methods of delay free systems. Moreover, the FSA and MSP scheme can lead to equivalent stabilize method for single input delay systems [19]. So, FSA is also sensitive to the method of distributed delay approximation [6]. This challenge will be deeper for unstable system with long time delay and uncertainty.

The main problem in these method roots in inflexibility of FSA and MSP due to uncertainty of model. This is because of the delay term of dead time systems is eliminated directly by them and they have significant challenge when face to uncertainty in system model.

To address this challenge, this paper presents a new robust state predictor that is based on state delayed observer. This predictor forecasts the state of system asymptotically. The parameters of proposed predictor can be set attending the weight of uncertainty and time delay. The state feedback is then designed applying the prediction state and the robust stability of closed loop system is proven. More importantly, proposed state predictor is extended to sequential sub-predictors (SSP) for unstable systems with a long time delay. SSP is founded on a collection of sub-predictors. The state of system is successively forecasted by each sub-predictor for a small part of delay, such that totally, SSP predicts the state for whole time delay. Consequently, the state feedback is calculated using SSP. Examples illustrate the ability of this method to stabilize dead time systems with long time delay and uncertainty.

## II. Problem statement and preliminaries

Consider linear input-delay uncertain system described by

$$\begin{cases} \dot{x}(t) = (A + \Delta A(t))x(t) + (B + \Delta B(t))u(t-d) \\ x(t) = \varphi(t) \quad \forall t \in [-d,0] \end{cases} \tag{1}$$

where $x \in \Re^n$, $u \in \Re^m$ and $d > 0$. The matrices $A$ and $B$ are known and time-varying bonded matrices $\Delta A$ and $\Delta B$ are described the uncertainty of this system where

$$[\Delta A \; \Delta B] = DJ(t)\,[E \; E_b] \tag{2}$$

$$J(t)^T J(t) \le I \tag{3}$$

The delay in the input prevents achieving stability for unstable systems with long time delay or significant uncertainty. Therefore, it is suggested to predict the state of this system to eliminate the delay in state feedback. In the other words, if $x(t+d) \approx x_p(t)$, then the delay in the controllable input can be compensated by using the predicted state instead of real state, i.e. $u(t-d) = Kx_p(t-d) \approx Kx(t)$.

The target goal in this paper is to suggest a robust control method to stabilize dead time system based on new robust predictor. Section 3 presents the simple form of this predictor and also investigates the calculation of the predictor parameters and controller gain. This method is extended to sequential sub-predictor for unstable systems with long time delay in Section 4. The predictor parameters and controller gain are also designed in this section. Examples show the capability of this method to stabilize dead time systems in Section 5. First, necessary lemma is presented as follows**.**

*Lemma 1:* [20] Given matrices $\Omega, \Gamma$ and $\Sigma$ of appropriate dimensions and with $\Omega$ symmetrical, then

$$\Omega + \Gamma J(\tau)\Sigma + \Sigma^T J(\tau)^T \Gamma^T < 0 \tag{4}$$

For all $F(\tau)$ satisfying $J(\tau)^T J(\tau) \le I$, if and only if there exists a scalar $\varepsilon > 0$ such that

$$\Omega + \varepsilon\Gamma\Gamma^T + \varepsilon^{-1}\Sigma^T\Sigma < 0 \tag{5}$$

## III. State predictor

In this section, the initial format of robust state predictor is presented as

$$\dot{\bar{x}}(t) = A\bar{x}(t) + Bu(t) + L(\bar{x}(t-d) - x(t)) \tag{6}$$

where $\bar{x} \in \Re^n$ is the predicted state that will forecast $x$ for $d$ seconds. Error is described by

$$e(t) = \bar{x}(t-d) - x(t) \tag{7}$$

The state of predictor forecasts the state of system if error converges to zero, i.e.

$$\bar{x}(t) \to x(t+d) \tag{8}$$

Now, the error dynamic equation can be calculated as

$$\dot{e}(t) = Ae(t) - \Delta Ax(t) + Le(t-d) - \Delta Bu(t-d) \tag{9}$$

The predictor matrix $L$ must be chosen such that the error converges to zero asymptotically. Following Theorem investigates the design of prediction parameter $L$ such that error equation converges to zero and calculation of the controller gain, $K$, to achieve robust closed loop stability.

*Theorem 1*: Consider system (1) with following control law.

$$\begin{cases} \dot{\bar{x}}(t) = A\bar{x}(t) + Bu(t) + L(\bar{x}(t-d) - x(t)) \\ u(t) = K\bar{x}(t) \end{cases} \tag{10}$$

Assume that $(A, B)$ is controllable. The closed-loop system is robust asymptotically stable and $\bar{x}$ predicts $x$ for $d$ second if there exist symmetric matrices $\overline{P}_0 > 0$, $\overline{P}_1 > 0$, $\overline{Q} > 0$, $\overline{S} > 0$, matrices $Y$, $U$, $M_1$, $F_0$ of appropriate dimensions, and scalar $\varepsilon$ such that the following inequality holds.

$$\begin{bmatrix} \Omega_{11} & \Omega_{12} & -\tilde{d}\overline{Y} & \tilde{d}\overline{P}\tilde{A}^T & \overline{P}\tilde{E}^T + F^T E_b{}^T \\ * & \Omega_{22} & -\tilde{d}\overline{U} & \tilde{d}M^T & 0 \\ * & * & -\tilde{d}\overline{P}\overline{S}^{-1}\overline{P} & 0 & 0 \\ * & * & * & -\tilde{d}\overline{S} + \varepsilon\tilde{D}\tilde{D}^T & 0 \\ * & * & * & * & -\varepsilon I \end{bmatrix} < 0 \tag{11}$$

where

$$\Omega_{11} = \overline{P}\tilde{A}^T + \tilde{A}\overline{P} + \overline{Y} + \overline{Y}^T + \overline{Q} + \varepsilon\tilde{D}\tilde{D}^T$$

$$\Omega_{12} = M - \overline{Y} + \overline{U}^T$$

$$\Omega_{22} = -\overline{Q} - \overline{U} - \overline{U}^T$$

And

$$\overline{P} = diag\{\overline{P}_0, \overline{P}_1\},\ \tilde{A} = diag\{A, A\},\ F = \begin{bmatrix} F_0 & 0 \end{bmatrix},\ \tilde{d} = d,$$

$$\tilde{B} = \begin{bmatrix} B \\ 0 \end{bmatrix},\ M = \begin{bmatrix} 0 & M_1 \\ 0 & M_1 \end{bmatrix},\ \tilde{D} = \begin{bmatrix} 0 \\ -D \end{bmatrix},\ \tilde{E} = \begin{bmatrix} E & -E \end{bmatrix}, \tag{12}$$

Moreover, $L$ and $K$ are given as:

$$K = P_0^{-1}F, \quad L = P_1^{-1}M_1 \tag{13}$$

*Proof*: By considering (7), the closed-loop system (1) and (10) can be rewritten as:

$$\dot{\tilde{x}}(t) = (\tilde{A} + \Delta\tilde{A} + \tilde{B}\tilde{K} + \Delta\tilde{B}\tilde{K})\tilde{x}(t) + \tilde{A}_h\tilde{x}(t - \tilde{d}) \tag{14}$$

where

$$\tilde{x} = \begin{bmatrix} \tilde{x}_1 = x + e \\ \tilde{x}_2 = e \end{bmatrix},\ \tilde{A}_h = \begin{bmatrix} 0 & L \\ 0 & L \end{bmatrix},\ \Delta\tilde{A} = \begin{bmatrix} 0 & 0 \\ -\Delta A & \Delta A \end{bmatrix},$$

$$\Delta\tilde{B} = \begin{bmatrix} 0 \\ -\Delta B \end{bmatrix},\ \tilde{K} = \begin{bmatrix} K & 0 \end{bmatrix}, \tag{15}$$

and $\tilde{A}$ and $\tilde{B}$ appear in (12). The stability of (14) is equivalent to closed loop system (1) and (10) and $\bar{x}$ approaches $x(t+d)$ if $\tilde{x}_2 = e(t)$ converge to zero asymptotically. A Lyapunov function is candidate to investigate the stability of (14) as follows.

$$V(\tilde{x}) = V_1(\tilde{x}) + V_2(\tilde{x}) + V_3(\tilde{x}) \tag{16}$$

where

$$V_1(\tilde{x}) = \tilde{x}(t)^T P\tilde{x}(t)$$

$$V_2(\tilde{x}) = \int_{-\tilde{d}}^{0} \int_{t+\beta}^{t} \dot{\tilde{x}}(\alpha)^T S\dot{\tilde{x}}(\alpha)\, d\alpha\, d\beta$$

$$V_3(\tilde{x}) = \int_{t-\tilde{d}}^{t} \tilde{x}(\alpha)^T Q\tilde{x}(\alpha) d\alpha \qquad (17)$$

By using Newton-Leibniz formula and free-weighting matrix (FWM), similar to the proof of Theorem 1 in [21], the derivative of $V(t)$ can be written as

$$\dot{V}(t) = \frac{1}{\tilde{d}} \int_{t-d}^{t} \xi(t,\alpha)^T \Lambda(\tilde{d})\xi(t,\alpha)d\alpha \qquad (18)$$

where

$$\xi(t,\alpha) = \begin{bmatrix} x(t)^T & x(t-\tilde{d})^T & x(\alpha)^T \end{bmatrix}^T$$

$$\Lambda(\tilde{d}) = \begin{bmatrix} \Xi_{11} & \Xi_{12} & -\tilde{d}Y \\ * & -Q-U-U^T+\tilde{d}\tilde{A}_h{}^T S\tilde{A}_h & -\tilde{d}U \\ * & * & -\tilde{d}S \end{bmatrix} \qquad (19)$$

where

$$\begin{aligned} \Xi_{11} &= (\tilde{A}+\Delta\tilde{A}+\tilde{B}\tilde{K}+\Delta\tilde{B}\tilde{K})^T P + P(\tilde{A}+\Delta\tilde{A}+\tilde{B}\tilde{K}+\Delta\tilde{B}\tilde{K}) \\ &\quad + d(\tilde{A}+\Delta\tilde{A}+\tilde{B}\tilde{K}+\Delta\tilde{B}\tilde{K})^T S(\tilde{A}+\Delta\tilde{A}+\tilde{B}\tilde{K}+\Delta\tilde{B}\tilde{K}) \\ &\quad + Y + Y^T + Q \end{aligned}$$

$$\Xi_{12} = P\tilde{A}_h - Y + U^T + d(\tilde{A}+\Delta\tilde{A}+\tilde{B}\tilde{K}+\Delta\tilde{B}\tilde{K})^T S\tilde{A}_h$$

Using Schur complement and Lemma 1, it is possible to show that $\Lambda(\tilde{d})$ is negative definite (i.e. $\dot{V}(t) < 0$ ) if following inequality holds.

$$\begin{bmatrix} \Psi_{11} & \Psi_{12} & -\tilde{d}Y & \tilde{d}\tilde{A}^T S & E^T + K^T E_b{}^T \\ * & \Psi_{22} & -\tilde{d}U & \tilde{d}\tilde{A}^T S & 0 \\ * & * & -\tilde{d}S & 0 & 0 \\ * & * & * & -\tilde{d}S + \varepsilon S\tilde{D}\tilde{D}^T S & 0 \\ * & * & * & * & -\varepsilon I \end{bmatrix} < 0 \qquad (20)$$

where

$$\Psi_{11} = \tilde{A}^T P + P\tilde{A} + Y + Y^T + Q + \varepsilon P\tilde{D}\tilde{D}^T P$$

$$\Psi_{12} = P\tilde{A}_h - Y + U^T$$

$$\Psi_{22} = -Q - U - U^T$$

Taking $\overline{P} = P^{-1} = diag\{\overline{P}_0, \overline{P}_1\}$, $\overline{S} = S^{-1}$, $\overline{Q} = P^{-1}QP^{-1}$, $\overline{Y} = P^{-1}YP^{-1}$, $\overline{U} = P^{-1}UP^{-1}$, pre- and post multiplying both sides of LMI (20) by $diag\{\overline{P},\overline{P},\overline{S},\overline{P},I\}$ and considering (13), it is possible to rewrite (20) as (11). □

Note that (11) is not linear due to $\overline{P}\,\overline{S}^{-1}\overline{P}$ term. The best idea to solve it without any limitation of degree of freedoms is reducing the original non-convex problem to an LMI-based nonlinear minimization problem. Then a modified cone complementarity linearization (CCL) algorithm [22] can be used to obtain a solution. This method is described in next section.

Theorem 1 may not be useful for unstable dead systems with a long time delay and weighty uncertainty (see examples in Section 5). To overcome this challenge, next section presents an extended form of this predictor called sequential sun-predictors. In this method, a series of sub-predictor is employed to each of them forecasts the state of system for small part of time delay.

## IV. SEQUENTIAL SUB -PREDICTORS

Long time delay may impede stabilizing of unstable systems with uncertainty using proposed predictor in Section 3 and it may exist no $L$ such that (11) is feasible. For this case, sequential sub-predictor (SSP) is suggested in this section. In SSP, time delay is divided to $R$ small part, and then a collection of successive sub-predictors are used to forecast the state for each small part of delay, $\overline{d}$, where

$$\overline{d} = \frac{d}{R}, \qquad R \in Z^+ \qquad (21)$$

The SSP is described by

$$\begin{cases} \dot{\overline{x}}_1(t) = A\overline{x}_1(t) + Bu(t-\overline{d}) \\ \qquad\qquad + L_1(\overline{x}_1(t-\overline{d}) - \overline{x}_2(t)) \\ \vdots \\ \dot{\overline{x}}_{R-1}(t) = A\overline{x}_{R-1}(t) + Bu(t-(R-2)\overline{d}) \\ \qquad\qquad + L_{R-1}(\overline{x}_{R-1}(t-\overline{d}) - \overline{x}_R(t)) \\ \dot{\overline{x}}_R(t) = A\overline{x}_R(t) + Bu(t-(R-1)\overline{d}) \\ \qquad\qquad + L_R(\overline{x}_R(t-\overline{d}) - x(t)) \end{cases} \qquad (22)$$

where $\overline{x}_i \in \Re^n, i = 1,\ldots,R$, Defining the prediction error as

$$\begin{cases} e_1(t) = \overline{x}_1(t-R\overline{d}) - \overline{x}_2(t-(R-1)\overline{d}) \\ \vdots \\ e_{R-1}(t) = \overline{x}_{R-1}(t-2\overline{d}) - \overline{x}_R(t-\overline{d}) \\ e_R(t) = \overline{x}_R(t-\overline{d}) - x(t) \end{cases} \qquad (23)$$

Note that $\overline{x}_1(t)$ predicts the $x(t+d)$, if all error equation converge to zero i.e.

$$e_t(t) = \overline{x}_1(t-R\overline{d}) - x(t) = e_1(t) + \cdots + e_R(t) \qquad (24)$$

The error dynamics are

$$\begin{cases} \dot{e}_1(t) = Ae_1(t) + L_1e_1(t-\overline{d}) - L_2e_2(t-\overline{d}) \\ \vdots \\ \dot{e}_{R-1}(t) = Ae_{R-1}(t) + L_{R-1}e_{R-1}(t-\overline{d}) - L_Re_R(t-\overline{d}) \\ \dot{e}_R(t) = Ae_R(t) - \Delta Ax(t) + L_Re_R(t-\overline{d}) - \Delta Bu(t-d) \end{cases} \qquad (25)$$

Following theorem investigates stability of closed loop system based on SSP. In this theorem, predictor parameters, $L_i$, and controller gain, $K$, will be calculated.

*Theorem 2*: Consider system (1) with following control law.

$$\begin{cases}\dot{\bar{x}}_1(t) = A\bar{x}_1(t) + Bu(t-\bar{d}) \\ \qquad\qquad + L_1(\bar{x}_1(t-\bar{d}) - \bar{x}_2(t)) \\ \vdots \\ \dot{\bar{x}}_R(t) = A\bar{x}_R(t) + Bu(t-(R-1)\bar{d}) \\ \qquad\qquad + L_R(\bar{x}_R(t-\bar{d}) - x(t)) \\ u(t) = K\bar{x}_1(t)\end{cases} \tag{26}$$

Assume that $(A,B)$ is controllable. The closed-loop system is robust asymptotically stable and $\bar{x}_1$ predicts $x$ for $d = R\bar{d}$ second if there exist symmetric matrices $\bar{P}_i > 0,\ i = 0,1,\cdots,R,$ $\bar{Q} > 0,\quad \bar{S} > 0$, matrices $Y,\ U,\ M_j,\ j = 1,\cdots,R,\ F_0$ of appropriate dimensions, and scalar $\varepsilon$ such that (11) holds, substituted

$$\bar{P} = diag\{\bar{P}_0, \bar{P}_1, \cdots, \bar{P}_R\},\ \tilde{A} = diag\{A, A, \cdots, A\},\ \tilde{d} = d/R,$$

$$\tilde{B} = \begin{bmatrix} B \\ 0 \\ \vdots \\ 0 \\ 0 \end{bmatrix},\ M = \begin{bmatrix} 0 & M_2 & 0 & \cdots & 0 \\ 0 & M_2 & -M_2 & \ddots & 0 \\ 0 & 0 & M_2 & \ddots & \vdots \\ \vdots & \ddots & \ddots & \ddots & -M_R \\ 0 & 0 & 0 & \cdots & M_R \end{bmatrix},\ \tilde{D} = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \\ -D \end{bmatrix},$$

$$F = \begin{bmatrix} F_0 & 0 & 0 & \cdots & 0 \end{bmatrix},\ \tilde{E} = \begin{bmatrix} -E & E & E & \cdots & E \end{bmatrix}. \tag{27}$$

Moreover, $L$ and $K$ are given as:

$$K = P_0^{-1}F, \quad L = P_j^{-1}M_j,\ j = 1,\cdots,R \tag{28}$$

*Proof*: By considering (23), the closed-loop system (1) and (26) can be rewritten as:

$$\dot{\tilde{x}}(t) = (\tilde{A} + \Delta\tilde{A} + \tilde{B}\tilde{K} + \Delta\tilde{B}\tilde{K})\tilde{x}(t) + \tilde{A}_h\tilde{x}(t-\tilde{d}) \tag{29}$$

where

$$\tilde{x} = \begin{bmatrix} \tilde{x}_1 = x + e_1 + \cdots + e_R \\ \tilde{x}_2 = e_1 \\ \vdots \\ \tilde{x}_R = e_R \end{bmatrix},\ \Delta\tilde{B} = \begin{bmatrix} 0 \\ \vdots \\ 0 \\ -\Delta B \end{bmatrix},$$

$$\tilde{A}_h = \begin{bmatrix} 0 & L_2 & 0 & \cdots & 0 \\ 0 & L_2 & -L_2 & \ddots & 0 \\ 0 & 0 & L_2 & \ddots & \vdots \\ \vdots & \ddots & \ddots & \ddots & -L_R \\ 0 & 0 & 0 & \cdots & L_R \end{bmatrix},\ \tilde{K} = \begin{bmatrix} K & 0 & \cdots & 0 \end{bmatrix}. \tag{30}$$

$\tilde{A}$ and $\tilde{B}$ appear in (27). The stability of (29) is equivalent to closed loop system (1) and (26) and $\bar{x}_1$ approaches $x(t+d)$ if $\tilde{x}_i$, $i = 2,\cdots,R$ converge to zero asymptotically, because $e_t(t) = \tilde{x}_2 + \cdots + \tilde{x}_R$. Based the same form of (29) and (14), proof can be followed same as proof of Theorem 1. □

To solve (11), using the modified CCL, from Schur complement, it is followed that (11) holds if

$$\begin{bmatrix} \Omega_{11} & \Omega_{12} & -\tilde{d}\bar{Y} & \tilde{d}\bar{P}\tilde{A}^T & \bar{P}\tilde{E}^T + F^T E_b{}^T \\ * & \Omega_{22} & -\tilde{d}\bar{U} & \tilde{d}M^T & 0 \\ * & * & -\tilde{d}\bar{T} & 0 & 0 \\ * & * & * & -\tilde{d}\bar{S} + \varepsilon\tilde{D}\tilde{D}^T & 0 \\ * & * & * & * & -\varepsilon I \end{bmatrix} < 0 \tag{31}$$

where

$$-\bar{P}\bar{S}^{-1}\bar{P} < -\bar{T} \tag{32}$$

Taking $T = \bar{T}^{-1}$, $S = \bar{S}^{-1}$, and $P = \bar{P}^{-1}$, from Schur complement (32) becomes

$$\begin{bmatrix} T & P \\ * & S \end{bmatrix} > 0 \tag{33}$$

The existence of a solution for (31) and (33) is a sufficiently condition for the feasibility of (11), imposing some degree of conservativeness. However, using this technique, the original of non-convex problem has been casted into the following LMI based non-linear minimization problem:

Minimize $Tr(T\bar{T} + P\bar{P} + S\bar{S})$, subject to (33) and

$$\begin{bmatrix} T & P \\ * & S \end{bmatrix} > 0,\ \begin{bmatrix} \bar{T} & I \\ * & T \end{bmatrix} > 0,\ \begin{bmatrix} \bar{S} & I \\ * & S \end{bmatrix} > 0,\ \begin{bmatrix} \bar{P} & I \\ * & P \end{bmatrix} > 0 \tag{34}$$

Then, the modified CCL algorithm is used to solve it and find the maximum possible $d$ as following procedure.

*Step 1*: Solve (31) and (34) for sufficiently small initial value of $\tilde{d}_0$ and find a feasible set $\{P_0, \bar{P}_0, S_0, \bar{S}_0, T_0, \bar{T}_0, \bar{Y}_0, \bar{U}_0, \bar{Q}_0, \cdots\}$ satisfying them. Set $j = 0,\ i = 0$.

*Step 2*: Solve the LMI (31) and (34) for all variables:

Minimize $Tr(T\bar{T}_i + \bar{T}T_i + P\bar{P}_i + \bar{P}P_i + S\bar{S}_i + \bar{S}S_i)$ subject to (31) and (34). Set $T_{i+1} = T$, $\bar{T}_{i+1} = \bar{T}$, $P_{i+1} = P$, $\bar{P}_{i+1} = \bar{P}$, $S_{i+1} = S$ and $\bar{S}_{i+1} = \bar{S}$.

*Step 3*: If (11) is satisfied and $d = \tilde{d}_i$ ($d = R\tilde{d}_i$ for Theorem 2), end. If (11) is not satisfied within a specified number of iterations ($j$), then exit with no solution. If (11) is satisfied but $d > \tilde{d}_i$ ($d > R\tilde{d}_i$ for Theorem 2), set $i = i + 1$, $j = 0$, increment $\tilde{d}_i$ and go to Step 2. Otherwise, set $i = i + 1$, $j = j + 1$ and go to Step 2.

Note that the number of sub-predictors, $R$ , can be set sufficiently big to (11) becomes feasible. In the other words, if (11) is not satisfied for $d$ in a usual number of CCL iterations, then R should be increased while it becomes feasible. Therefore this method can stabilize all unstable systems with long time delay and significant uncertainty. Next section presents a few examples to illustrate the capability of this method to stabilize unstable dead time systems with time varying uncertainty.

## V. Simulation Results

In this section a few examples are presented to shows the ability SSP to closed loop stability of dead time systems due to unstability of system, time delay value and weight of uncertainty.

*Example 1*: Consider system $\dot{x} = ax + bu(t-d)$ , where $a, b$ is scalar. SSP can forecast the states of systems for maximum delay $d = Rd_m$ that is shown in Table 1 (for iteration number 40 and increment and increment delay step 0.01).

Table 1: Maximum possible delay to prediction of state

| $d = Rd_m$ | $R = 1$ | $R = 2$ | $R = 3$ | $R = 4$ | $R = 5$ |
|---|---|---|---|---|---|
| $a = -1$ | $\infty$ | $\infty$ | $\infty$ | $\infty$ | $\infty$ |
| $a = 0.2$ | 4.93 | 9.77 | 14.55 | 19.33 | 23.05 |
| $a = 0.5$ | 1.96 | 3.85 | 5.72 | 7.56 | 9.13 |
| $a = 1$ | 0.97 | 1.90 | 2.8 | 3.69 | 4.51 |
| $a = 2$ | 0.48 | 0.93 | 1.36 | 1.78 | 2.15 |

Table 1 shows that maximum possible delay to stabilize of closed loop system is directly proportional to $R$ and inversely proportional to $a$. Although the increasing the $a$, limits the bound of delay, but it is possible to compensate it by increasing the number of sub-predictor.

*Example 2*: Consider an unstable uncertain system with integrator term and non-minimum phase zero, defined as

$$\begin{cases} \dot{x}(t) = \begin{bmatrix} 0 + .02\sin(t) & 0 \\ 0 & 0.5 + .02\sin(t) \end{bmatrix} x(t) + \begin{bmatrix} 2 \\ -2 \end{bmatrix} u(t-3) \\ y(t) = \begin{bmatrix} -1 & 1 \end{bmatrix} x(t), \qquad x(0) = \begin{bmatrix} 1 & 0 \end{bmatrix}^T \end{cases}$$

Using Theorem 2, the controller gain and SSP matrices are calculated as:

$$K = \begin{bmatrix} 1.15 & 4.59 \end{bmatrix}, \; L_1 = \begin{bmatrix} -0.04 & 0.12 \\ -0.05 & -0.86 \end{bmatrix},$$

$$L_2 = \begin{bmatrix} -0.08 & 0.23 \\ -0.01 & -0.82 \end{bmatrix}, \; L_3 = \begin{bmatrix} -0.2 & 0.34 \\ -0.01 & -0.70 \end{bmatrix},$$

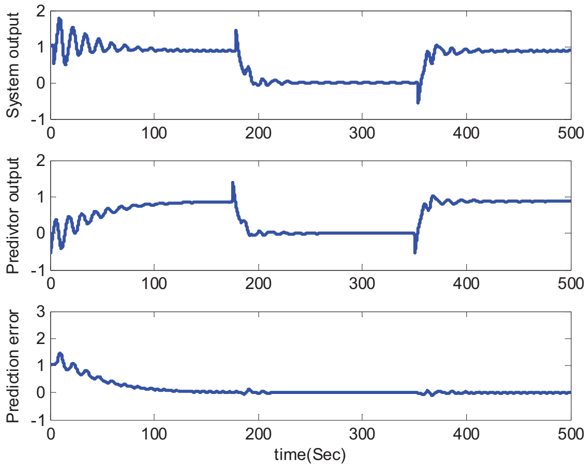

Figure.1 Pulse response of closed loop system

Note that the initial conditions of system are unknown in prediction and the initial conditions of SSP are set to zero. Figure 1 illustrates the pulse response of the closed loop system. This example shows the capability of this method to stabilize uncertain and unstable dead time systems with a long time delay.

## VI. Conclusion

This paper suggests a method to stabilize uncertain dead time systems based on a new robust predictor. Moreover, this method is applied for unstable dead time systems with a long time delay by sequential sub-predictors. The main idea in this predictor is composed of a series of sub-predictor; each of them is for a partition of long time delay. This method can improve the flexibility of predictor to overcome any weight uncertainty. This method also can apply for nonlinear systems and output feedback that will be presented in future works.

*Abstract*— **In this paper, an on-line identification scheme is proposed to enhance the residual state error performance in face of disturbances. The proposed scheme is based on an $e_1$-modification adaptive law for the weights to approximate the unknown nonlinearities with bounded error. Besides, an identification model with feedback is introduced to improve the state error performance. The feedback is based on a bounding function to estimate an upper bound for the disturbances. Via an adaptive bounding technique and Lyapunov methods, it is proved that the residual state error performance is practically immune to disturbances. To validate the theoretical results, the identification of a four-order generalized Lü hyperchaotic system is performed.**

## I. INTRODUCTION

The use of neural networks (NNs) paradigm as a powerful tool for identification of uncertain nonlinear systems has encouraged, starting from the 90s, several heuristic and theoretical studies, see for instance [1]-[8] and the references therein. This interest is motivated by the capability of the NNs to learn complex input-output mappings, since they are universal approximators, and by the inevitable presence of uncertainties in modeling problems, due to the simplification imposed by the mathematical modeling, unexpected faults, changes in operation conditions, aging of equipment, and so on. On the other hand, system neuro-identification is important not only to predict the behavior of the system, but also for providing an appealing system parameterization, which can later be used in the synthesis of control algorithms, since mathematical characterization is often a prerequisite to controller design.

Neural identification models usually employed are the dynamic ones, being their weights mainly adjusted by using gradient and backpropagation algorithms or their robust modifications [1], [3]-[8]. Most used robust modifications in neuro-identification are the $\sigma$, switching- $\sigma$, $\varepsilon_1$, parameter projection, and dead zone [3]-[8] which avoid the parameter drift. Nevertheless, to the best of our knowledge, at present most of learning algorithms for neuro-identification ensure that the residual state error is related directly to upper bounds for the approximation error, ideal weight and disturbances.

For instance in [3], the identification of a general class of uncertain continuous-time dynamical systems was proposed, and a $\sigma$ -modification adaptive law for the weights of recurrent high-order neural networks (RHONNs) was chosen to ensure that the state error converges to the neighborhood of the origin, whose radius depends directly of the approximation error and disturbances. In [4], dynamic NNs based on two-layer neural networks were used to identify a general class of uncertain nonlinear systems. It was shown that in the presence of disturbances the state error is uniformly ultimately bounded where the ultimate bound is directly proportional to an upper bound of the disturbance. In [5], the identification of delayed nonlinear system was investigated. By using identification models based on delayed neural networks with learning laws for the weights designed using a Lyapunov-Krasovskii approach, it was shown that the state error is upper bounded by a constant which depends directly of the disturbance. More recently, also others relevant works, such as [6]-[7], shown that discrete high-order neural networks and dynamic neural networks with two different time scales, respectively, can be used to identify nonlinear systems with bounded errors, which are straightforwardly related to the disturbances.

From the discussion above, observe that most of neuro-identification schemes ensure a state error performance that is directly related to the disturbance. In practice, uncertainties are inevitable, hence it is desirable to propose identification schemes with improved state error performance in face of disturbances. This is the main motivation for this paper.

Hence, in this paper we propose a neuro-identification algorithm in which the residual state error is inversely correlated with the disturbances to make the residual state error performance practically immune to disturbances. To this end, based on an adaptive bounding technique [9] and Lyapunov methods [10], a neural identification model with explicit feedback based on a bounding function is proposed. The aim is to approximate an upper bound for the disturbances, which is used in the stability proof, to make the Lyapunov derivative ($\dot{V}$ ) negative semi-definite practically in all error space, since bounding functions can be used to dominate positive terms in $\dot{V}$ and hence improve the performance.

## II. LINEARLY PARAMETERIZED NEURAL NETWORKS

Linearly parameterized neural networks (LPNNs) can be expressed mathematically as

978-1-4673-1560-9/12/$31.00 ©2012 IEEE

$$\rho_{nn}(W,\zeta)=W\pi(\zeta) \qquad (1)$$

where $W\in\Re^{n\times L_\rho}$, $\zeta\in\Re^{L_\zeta}$, $\pi:\Re^{L_\zeta}\mapsto\Re^{L_\rho}$ is the so-called basis function vector, which can be considered as a nonlinear vector function whose arguments are preprocessed by a scalar function $s(\cdot)$, and $n,L_\rho,L_\zeta$ are integers strictly positive. Commonly used scalar functions $s(\cdot)$ include sigmoid, tanh, gaussian, Hardy's, inverse Hardy's multiquadratic, etc [8]. However, here we are only interested in the class of LPNNs for which $\pi(\cdot)$ is bounded, since in this case we have,

$$\|\pi(\zeta)\|\le\pi_0 \qquad (2)$$

being $\pi_0$ a strictly positive constant.

The class of LPNNs considered in this work includes HONN [3], RBF networks [8], wavelet networks [11], and also others linearly parameterized approximators as Takagi-Sugeno fuzzy systems [12]. Universal approximation results in [8], [11]-[12] indicate that:

***Property 1***: Given a constant $\varepsilon_0>0$ and a continuous function $f:\Omega\mapsto\Re^n$, where $\Omega\subset\Re^{L_\zeta}$ is a compact set, there exists a weight matrix $W=W^*$ such that the output of the neural network architecture (where $L_\rho$ may depend on $\varepsilon_0$ and $f$ ) satisfies

$$\sup_{\zeta\in\Omega}\left|f(\zeta)-W^*\pi(\zeta)\right|\le\varepsilon_0 \qquad (3)$$

where $|\cdot|$ denotes the absolute value if the argument is a scalar. If the argument is a vector function in $\Re^n$ then $|\cdot|$ denotes any norm in $\Re^n$.

## III. Problem formulation

Consider the following nonlinear differential equation

$$\dot{x}=F(x,u,v,t), \qquad x(0)=x_0 \qquad (4)$$

where $x\in X$ is the *n*-dimensional state vector, $u\in U$ is a *m*-dimensional admissible input vector, $v\in V\subset\Re^q$ is a vector of time varying uncertain variables and $F:X\times U\times V\times[0,\infty)\mapsto\Re^n$ is a continuous map. In order to have a well-posed problem, we assume that $X,U,V$ are compact sets and $F$ is locally Lipschitzian with respect to *x* in $X\times U\times V\times[0,\infty)$, such that (4) has a unique solution.

We assume that the following can be established

***Assumption 1:*** On a region $X\times U\times V\times[0,\infty)$

$$\|h(x,u,v,t)\|\le h_0 \qquad (5)$$

where

$$h(x,u,v,t)=F(x,u,v,t)-f(x,u) \qquad (6)$$

$f$ is an unknown map, *h* are internal or external disturbances, and $\bar{h}_0$, such that $\bar{h}_0>h_0\ge0$, is a known constant.

Hence, except for the Assumption 1, we say that $F(x,u,v,t)$ is an unknown map and our aim is to design a NNs-based identifier for (4) to ensure that the residual state error is ultimately bounded with ultimate bound which is, practically, not affected by the disturbances.

## IV. Identification model and state error equation

We start by presenting the identification model and the definition of the relevant errors associated with the problem.

Let $\bar{f}$ be the best known approximation of *f*, $P\in\Re^{n\times n}$ a scaling matrix defined as $P=P^T>0$, $\bar{g}=P^{-1}g$, and $g(x,u)=f(x,u)-\bar{f}(x,u)$. Then, by adding and subtracting $\bar{f}(x,u)$, (4) can be rewritten as

$$\dot{x}=\bar{f}(x,u)+P\bar{g}(x,u)+h(x,u,v,t) \qquad (7)$$

***Remark 1:*** It should be noted that if the designer has no previous knowledge of *f*, then $\bar{f}$ is simply assumed as being the zero vector.

From (7), by using LPNNs, the nonlinear mapping $\bar{g}(x,u)$ can be replaced by $W^*\pi(x,u)$ plus an approximation error term $\varepsilon(x,u)$. More exactly, (7) becomes

$$\dot{x}=\bar{f}(x,u)+PW^*\pi(x,u)+P\varepsilon(x,u)+h(x,u,v,t) \quad (8)$$

where $W^*\in\Re^{nxL}$ is an "optimal" or ideal matrix, which can be defined as

$$W^*:=\arg\min_{\hat{W}\in\Gamma}\left\{\sup_{\substack{x\in X,\\ u\in U}}\left|\bar{g}(x,u)-\hat{W}\pi(x,u)\right|\right\} \qquad (9)$$

with $\Gamma=\left\{\hat{W}\ \middle|\ \|\hat{W}\|\le\alpha_{\hat{W}}\right\}$, $\alpha_{\hat{W}}$ is a strictly positive constant, $\hat{W}$ is an estimate of $W^*$, and $\varepsilon(x,u)$ is an approximation error term, corresponding to $W^*$, which can be defined as

$$\varepsilon(x,u):=\bar{g}(x,u)-W^*\pi(x,u) \qquad (10)$$

The approximation, reconstruction, or modeling error $\varepsilon$ in (10) is a quantity that arises due to the incapacity of LPNNs to match the unknown map $\bar{g}(x,u)$. Since *X*, *U* are compact sets and from (2), the following can be established

***Assumption 2:*** The Frobenius matrix norm $\left\|W^*-W_0\right\|_F$, where $W_0\in\Re^{nxL}$ is upper bounded by a known positive constant $\overline{\beta}$, such that

$$\left\| W^{*} - W_0 \right\|_F \leq \overline{\beta} \tag{11}$$

***Assumption 3:*** On a region $X \times U$ , the approximation error is upper bounded by

$$\left\| \varepsilon(x,u) \right\| \leq \varepsilon_0 \tag{12}$$

where $\bar{\varepsilon}_0$, such that $\bar{\varepsilon}_0 > \varepsilon_0 \geq 0$ , is an known constant.

***Remark 2:*** Assumption 1 is usual in identification. Assumption 2 is quite natural since $\overline{g}$ is continuous and their arguments evolve on compact sets.

***Remark 3:*** Note that any $\bar{\pi}_0 > \pi_0$ , $\bar{h}_0 > h_0$ , and $\bar{\varepsilon}_0 > \varepsilon_0$ also satisfy (2), (5), and (12). Hence, to avoid confusion, we define $\pi_0$, $h_0$, and $\varepsilon_0$ to be the smallest constants such that (2), (5), and (12) are satisfied.

***Remark 4***: It should be noted that $W^{*}$ and $\varepsilon(x,u)$ might be nonunique. However, the uniqueness of $\left\|\varepsilon(x,u)\right\|$ is ensured by (9).

***Remark 5:*** It should be noted that $W^{*}$ was defined as being the value of $\hat{W}$ that minimizes the $L_\infty$ - norm difference between $\overline{g}(x,u)$ and $\hat{W}\pi(x,u)$. The scaling matrix *P* from (7) is introduced to manipulate the magnitude of uncertainties and hence the magnitude of the approximation error. This procedure improves the performance of the identification process.

***Remark 6:*** Notice that the proposed neuro-identification scheme is a black-box methodology, hence the external disturbances and approximation error are related. Based on the system input and state measurements, the uncertain system (including the disturbances) is parameterized by a neural network model plus an approximation error term. However, the parameterization (8) is motivated by the fact that neural networks are not adequate for approximating external disturbances, since the basis function depends on the input and states, whereas the disturbances depend on the time and external variables. The aim for presenting the uncertain system in the form (8), where the disturbance *h* is explicitly considered, is also to highlight that the proposed scheme is in addition valid in the presence of unexpected changes in the systems dynamics that can emerge, for instance, due to environment change, aging of equipment or faults.

Based on structure (8) and to ensure improved state error performance, the identification model is chosen as

$$\dot{\hat{x}} = \bar{f}(x,u) + P\hat{W}\pi(x,u) - \left(l_0\hat{\psi} + \psi_0^2 P/4\right)(\hat{x} - x) \tag{13}$$

where $\hat{x}$ is the estimated state, $\hat{\psi}$ is a bounding scalar function, $l_0$ and $\psi_0$ are positive constants. It will be demonstrated that the identification model (13) used in conjunction with a convenient adjustment laws for $\hat{W}$ and $\hat{\psi}$, to be proposed in the next section, improve the residual state error performance in the presence of disturbances.

***Remark 7:*** It should be noted that in our formulation, the LPNN is only required to approximate $P^{-1}\left[f(x,u) - \bar{f}(x,u)\right]$ (whose magnitude is often small) instead of the entire function $P^{-1}\left[f(x,u)\right]$ . Hence, standard identification methods (to obtain some previous $\bar{f}$ ) can be used together with the proposed algorithm to improve performance.

By defining the state estimation error as $\tilde{x} := \hat{x} - x$ , from (8) and (13), we obtain the state estimation error equation

$$\dot{\tilde{x}} = P\tilde{W}\pi(x,u) - \left(l_0\hat{\psi} + \psi_0^2 P/4\right)\tilde{x} - P\varepsilon(x,u) - h(x,u,v,t) \tag{14}$$

where $\tilde{W} := \hat{W} - W^{*}$ .

## V. ADAPTIVE LAWS AND STABILITY

Before presenting the main theorem, we state a fact, which will be used in the stability analysis.

***Fact 1:*** Let $W^{*}, W_0, \hat{W}, \tilde{W} \in \Re^{n \times L_p}$ . Then, with the definition of $\tilde{W} = \hat{W} - W^{*}$ , the following equalities are true:

$$\begin{aligned} 2tr\left[\tilde{W}^T\left(\hat{W} - W_0\right)\right] = \left\|\tilde{W}\right\|_F^2 \\ + \left\|\left(\hat{W} - W_0\right)\right\|_F^2 - \left\|\left(W^{*} - W_0\right)\right\|_F^2 \end{aligned} \tag{15}$$

We now state and prove the main theorem of the paper.

***Theorem 1:*** Consider the class of nonlinear systems described by (4) and the Assumptions 1-3. Let the identification model be given by (13) with

$$\dot{\hat{W}} = -\gamma_W [\gamma_0 (\hat{W} - W_0) \left\|\tilde{x}\right\| + 2\tilde{x}\pi^T(x,u)] \tag{16}$$

and

$$\dot{\hat{\psi}} = -\gamma_\psi \left[\psi_0\hat{\psi}\left\|\tilde{x}\right\| - \psi_0\left\|\tilde{x}\right\| - \psi_2 l_0 \left\|\tilde{x}\right\|^2\right] , \hat{\psi}(0) > 0 \tag{17}$$

where

$$\gamma_\psi > 0, \quad \psi_2 = 2\lambda_{\min}\left(P^{-1}\right), \tag{18}$$

$$\psi^* = 1 - \frac{1}{\psi_0}\left[\psi_0^2 - 2\psi_0\left(2\bar{\varepsilon}_0 + 2\bar{h}_0\left\|P^{-1}\right\|_F + \gamma_0\bar{\beta}^2/2\right)\right]^{\frac{1}{2}}$$

Then, the signal errors $\tilde{W}, \tilde{\psi}$ are uniformly bounded and the state error $\tilde{x}$ is uniformly ultimately bounded.

***Proof:*** Consider the Lyapunov function candidate

$$V = \tilde{x}^T P^{-1}\tilde{x} + tr\left(\tilde{W}^T \gamma_W^{-1}\tilde{W}\right)/2 + \gamma_\psi^{-1}\tilde{\psi}^2/2 \qquad (19)$$

where $\tilde{W} = \hat{W} - W^*$ and $\tilde{\psi} = \hat{\psi} - \psi^*$.

By evaluating (19) along the trajectories of (14), (16) and (17), we obtain

$$\begin{aligned}\dot{V} &= 2\tilde{x}^T\tilde{W}\pi - 2l_0\hat{\psi}\tilde{x}^T P^{-1}\tilde{x} - 2\tilde{x}^T\varepsilon - 2\tilde{x}^T P^{-1}h \\ &- \gamma_0 \| \tilde{x} \| tr[\tilde{W}^T(\hat{W} - W_0)] - 2tr(\tilde{W}^T\tilde{x}\pi^T) \\ &- \psi_0 \| \tilde{x} \| \tilde{\psi}\hat{\psi} + \psi_0\tilde{\psi} \| \tilde{x} \| + \psi_2 l_0\tilde{\psi} \| \tilde{x} \|^2 - \psi_0^2\left\|\tilde{x}\right\|/2\end{aligned} \qquad (20)$$

Furthermore, by using the representations $tr\left(\tilde{W}^T\tilde{x}\pi^T\right) = \tilde{x}^T\tilde{W}\pi$ and $2\tilde{\psi}\hat{\psi} = \tilde{\psi}^2 + \hat{\psi}^2 - \psi^{*2}$, the fact 1 and the definition (18), (20) can be upper bounded as

$$\begin{aligned}\dot{V} \le &- l_0\psi_2\hat{\psi} \| \tilde{x} \|^2 + (2\bar{\varepsilon}_0 + 2\bar{h}_0 \| P^{-1} \|_F) \| \tilde{x} \| \\ &- \gamma_0 \| \tilde{x} \| \| \tilde{W} \|_F^2/2 + \gamma_0 | W^* - W_0 \|_F^2 \| \tilde{x} \|/2 \\ &- \psi_0 \| \tilde{x} \| (\tilde{\psi}^2 + \hat{\psi}^2 - \psi^{*2})/2 + \psi_0\tilde{\psi} \| \tilde{x} \| \\ &+ \psi_2 l_0\tilde{\psi} \| \tilde{x} \|^2 - \psi_0^2 \| \tilde{x} \|^2/2\end{aligned} \qquad (21)$$

By employing the definitions of $\psi_2$ and $\psi^*$, see (18), and recalling that $\tilde{\psi} = \hat{\psi} - \psi^*$, (21) implies

$$\dot{V} \le -\psi_2 l_0\psi^*\left\|\tilde{x}\right\|^2 + \psi_0\hat{\psi}\left\|\tilde{x}\right\| - \psi_0\left\|\tilde{x}\right\|\hat{\psi}^2/2 - \psi_0^2\left\|\tilde{x}\right\|^2/2 \qquad (22)$$

Since $\hat{\psi} \le \hat{\psi}^2/2 + 1/2$, we arrive at

$$\dot{V} \le -(\psi_2 l_0\psi^* + \frac{\psi_0^2}{2})\left\|\tilde{x}\right\|^2 + \psi_0\left\|\tilde{x}\right\|/2 \qquad (23)$$

Hence, $\dot{V} < 0$ as long as

$$\left\|\tilde{x}\right\| > \frac{\psi_0}{2\psi_2 l_0\psi^* + \psi_0^2} := \alpha \qquad (24)$$

Thus, since α is constant, by using Lyapunov arguments [10], we concluded that $\tilde{x}$ are uniformly ultimately bounded, with ultimate bound α. Based on (16) and (17) $\tilde{W}, \tilde{\psi}$ are also bounded. Note that if, by any reason, $\| \tilde{x} \|$ escapes of the residual set Ω, where $\Omega = \{ \tilde{x} \mid \| \tilde{x} \| \quad \alpha \}$, $\dot{V}$ becomes negative definite again, and force the convergence of the state error to the ball of radius $\alpha$.

□

***Remark 8:*** The existence of $\psi^*$ is guaranteed as long as $\psi_0 \ge 2\bar{\varepsilon}_0 + 2\bar{h}_0\left\|P^{-1}\right\|_F + \gamma_0\bar{\beta}/2$. However, it is a mild condition, since any increase of $\psi_0$ has only a positive impact on the residual state error, as can be seen in (24).

***Remark 9:*** Since the ultimate bound $\alpha$ is inversely proportional to $\psi^*$, which depends on an upper bound for the disturbances, see (18), the performance of the proposed method cannot be adversely affected by the increase of disturbances.

***Remark 10:*** It should be noted that $\psi^*$ might be nonunique. In fact,

$$\psi^* = 1 + \frac{1}{\psi_0}\left[\psi_0^2 - 2\psi_0\left(2\bar{\varepsilon}_0 + 2\bar{h}_0\left\|P^{-1}\right\|_F + \gamma_0\bar{\beta}^2/2\right)\right]^{\frac{1}{2}} \qquad (25)$$

also satisfy (22). However, note from (24) that the ultimate bound for the residual state error is practically of order $1/\psi_0$ for large $\psi_0$. Hence, the residual state error is, practically, not affected by disturbances, as long as the design constants are adequately selected. The above mentioned peculiarity, to the best of our knowledge, is the main advantage of the proposed scheme in comparison with the literature.

## IV. Simulations

To illustrate the application of the proposed scheme, we consider a generalized Lü hyperchaotic system described by [13], [14]

$$\begin{aligned}\dot{\bar{x}} &= a\left(y - \bar{x}\right) + u_{\bar{x}} + d_{\bar{x}} \\ \dot{y} &= b\bar{x} - k\bar{x}z + \omega + u_y + d_y \\ \dot{z} &= -cz + l\bar{x}^2 + u_z + d_z \\ \dot{\omega} &= -d\bar{x} + u_\omega + d_\omega\end{aligned} \qquad (26)$$

where $a$, $b$, $c$, $d$, $l$ and $k$ are constant parameters, $u_{\bar{x}}, u_y, u_z$ and $u_\omega$ are control inputs, and $d_{\bar{x}}, d_y, d_z$ and $d_\omega$ are unknown disturbances. It was considered that $a$=10, $b$=40, $c$=2.5, $d$=10.6, $k$=1 and $l$=4. Notice that system (26) satisfies Assumptions 1-3, since the state variables evolved on compact sets.

To identify the uncertain system (26) the proposed identification model (13) and the adaptive laws (16) and (17) were implemented. The initial conditions for the hyperchaotic system and the identification model were $\bar{x}(0)=-4,\ y(0)=-8,\ z(0)=-6,\quad \omega(0)=12$ and $\hat{x}(0)=0,$ in order to evaluate the performance of the proposed algorithm under adverse initial conditions.

The others design parameter were chosen as $u$=0,

$$\gamma_W=9,\ \gamma_0=2.5, \psi_0=50, \psi_1=10,$$
$$lo=10,\ s(\cdot)=10/[1+\exp-0.5(\cdot)],$$

$$\pi=\left[s(\bar{x}); s(y); s(z); s(\omega); s^2(\bar{x}); s^2(y); s^2(z); s^2(\omega)\right],$$

$$P=\begin{bmatrix}100 & 0 & 0 & 0\\ 0 & 50 & 0 & 0\\ 0 & 0 & 100 & 0\\ 0 & 0 & 0 & 100\end{bmatrix},$$

and $P=\begin{bmatrix}1 & 0 & 0 & 0 & 0 & 0 & 0 & 0\\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0\\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0\end{bmatrix}.$

By keeping all design parameters as before, we introduced disturbances at $t=0.1$ in order to check the robustness for the proposed method. Two cases are considered:

a) $h_1(x,t)=\eta\left[e^{0.1t}\quad 2\sin(5t)\quad e^{0.1t}\cos(t)\quad 0.1\log(10+2\eta)\right]^T$

b) $h_2(x,t)=\eta[\sin(t)\quad 1.2\sin(2t)\quad \cos(4t)\quad 1.5\sin(t)]^T,$

where $\eta=0.5\|x\|$ and $x=[\bar{x}\quad y\quad z\quad \omega]^T$.

It should be noted that the last disturbance $h_1$ is unbounded as $t\to\infty$. However, it was considered here in order to evaluate the residual state error performance in the presence of severe disturbances.

The performances in the estimation of the states $\bar{x}, y, z$ and $\omega$ when disturbance $h_1$ is present are shown in Figures 1-5, and when disturbance $h_2$ is present is shown in Figure 6. We can see that the simulations confirm the theoretical results, that is, the algorithm is stable and the residual state error was, practically, not affected by the disturbance in $t=0.1\,\text{s}$.

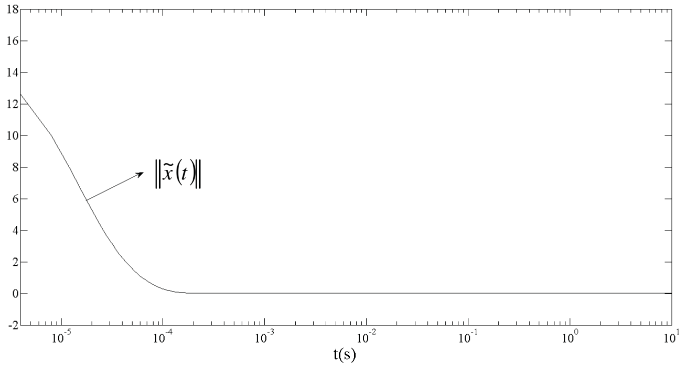

Figure 6. State error norm performance for disturbance $h_2$.

## V. Conclusions

In this work, by using Lyapunov analysis and an adaptive bounding technique, we have proposed an on-line identification scheme which presents an improved tolerance in face of disturbances. The proposed algorithm is based on a $\varepsilon_l$-modification and uses an explicit feedback on the identification model to improve residual state error performance. A simulation example showed the effectiveness of the proposed method.

*Abstract*—**This study concerns output consensus problems of linear multi-agent systems with fixed topologies and agents described by homogeneous or heterogeneous linear systems. Based on generalized inverse, graph and linear system theory, conditions are investigated for output consensusability with respect to a set of admissible consensus protocols. The given output consensus conditions depend on both topologies within linear multi-agent systems and structure properties of each agent's dynamic. The designed output feedback control law can guarantee output consensusability of the considered linear multi-agent systems with respect to a given admissible set. A provided example illustrates applicability of the proposed approach.**

## I. Introduction

In recent years, consensus problems in multi-agent systems have received intensive attention from many fields including physics, biology and control theory and engineering due to their numerous and various applications in these areas [1]–[3]. The consensus problem is one of the most fundamental distributed coordination control problems of multi-agent networks. Roughly speaking, consensus means that multiple agents reach an agreement on a common value which might be, for example, the altitude in multi-spacecraft alignment, heading direction in flocking behavior, or average in distributed computation [4]. Numerous results have been obtained in consensus problems from different perspectives [5]–[14]. For phase transition of a group of self-driven particles, a simple and popular model has been proposed by using graph theory [2]. Numerically it has been demonstrated that all agents move in the same direction eventually. Attitude alignment has been studied for the network of agents with an undirected graph in which each agent has a discrete-time integrator dynamic [5]. Moreover, [5] has provided a theoretical explanation for the model in [2]. Many researchers have applied reinforcement learning to multi-agent systems, and these results show that reinforcement learning can perform well in multi-agent systems [6]. For first-order discrete-time multi-agent systems with time-varying topologies and stochastic communication noises, average-consensus conditions for distributed stochastic approximation type protocols have been proposed by using probability limit theory and algebraic graph theory [7]. Several dynamic consensus algorithms for second-order multi-agent systems and sufficient conditions for state consensus of the system have been proposed in [8] and [9]. Based on matrix theory, algebraic graph theory and Lyapunov control approach, [10] has derived some sufficient conditions to achieve second-order consensus for multi-agent systems with directed topology and nonlinear dynamic. A class of nonlinear high-order multi-agent systems have been studied and achieved consensus even though the communication graph which has no spanning tree [11]. To solve the consensus problem of multi-agent systems with a time-invariant communication topology and agents described by linear time-invariant systems, the necessary and sufficient condition has been given, which can guarantee the existence of an observer-type protocol solving the consensus problem, meanwhile, under this condition, an unbounded consensus region has been yielded if and only if each agent is both stabilizable and detectable [12]. [15] has provided necessary and sufficient state consensus conditions with respect to a set of admissible consensus protocols for descriptor multi-agent systems with fixed topologies.

In fact, most of existing results have investigated in consensus problems for multi-agent systems described by homogeneous agents. Comparing the discussion of consensus problems for homogeneous multi-agent systems with that for heterogeneous ones, it is easy to see that the later one has more significant due to heterogeneous multi-agent systems have more extensive description in the real world. However, rare works have been published to deal with consensus problems for multi-agent systems consisting of heterogeneous agents [16]–[18]. [16] has given state consensus conditions using tools of graph, algebra and descriptor linear system theory for descriptor multi-agent systems with agents described by homogeneous or heterogeneous descriptor systems. For heterogeneous and nonlinear multi-agent systems with topologies changing in an intermittent and arbitrary way, the necessary and sufficient condition of cooperative controllability has been proposed by using matrix-theoretical approach [17]. [18] has studied output consensus problems for a class of heterogeneous multi-agent systems consisting of uncertain linear SISO systems. Thus, this paper investigates output consensus problem for a class of multi-agent systems consisting of homogeneous or heterogeneous linear systems. Based on graph, generalized inverse and linear system theory, output consensus conditions are proposed. And designing the output feedback control law can guarantee that the studied system is output consensusable with respect to an admissible set.

*Notation:* For the given vector or matrix $X$, $\|X\|$ represents the Euclidean norm of $X$. Let $\sigma(A)$ be the set of all eigenvalues of the square matrix $A$. $\mathbb{C}^-$ represents the open left-half

complex plane.

## II. Preliminaries and Problem Formulation

In general, information exchange between agents in a multi-agent system can be modeled by directed or undirected graphs [19]. Similar to [20], let $\mathcal{G} = (\mathcal{V}, \mathcal{E}, \mathcal{A})$ be a weighted digraph with the set of vertices $\mathcal{V} = \{1, 2, \cdots, N\}$ and the set of edges $\mathcal{E} \subseteq \mathcal{V} \times \mathcal{V}$. In $\mathcal{G}$, the $i$-th vertex represents the $i$-th agent, and a directed edge from $i$ to $j$ is denoted as an ordered pair $(i, j) \in \mathcal{E}$, which means that agent $j$ can directly receive information from agent $i$. In this case, the vertex $i$ is called the parent vertex and the vertex $j$ is called the child vertex. The set of neighbors of the $i$-th agent is denoted by $N_i = \{j \in \mathcal{V} | (j, i) \in \mathcal{E}\}$. And the weighted adjacency matrix $\mathcal{A} = [a_{ij}] \in \mathbb{R}^{N\times N}$ with nonnegative elements, and $a_{ii} = 0, a_{ij} > 0 \Leftrightarrow j \in N_i$, otherwise $a_{ij} = 0$.

**Definition** *2.1:* [21] Let $A \in \mathbb{C}^{m\times n}$. Then the matrix $X \in \mathbb{C}^{n\times m}$ satisfying the following four equations (usually called the Penrose conditions)

$$AXA = A,\ XAX = X,\ (AX)^* = AX,\ (XA)^* = XA$$

is called the Moore-Penrose inverse of $A$, and is denoted by $X = A^\dagger$.

**Lemma** *2.1:* [21] Let $A \in \mathbb{C}^{m\times n}$. The generalized inverse $X$ satisfying the Penrose conditions is existent and unique. Moreover, if rank$A = n$, then $A^\dagger A = I_n$; if rank$A = m$, then $AA^\dagger = I_m$.

Consider a linear multi-agent system consisting of $N$ agents indexed by $1, 2, \cdots, N$, respectively. The dynamics of the $i$-th agent is described by homogeneous or heterogeneous linear systems

$$\dot{x_i}(t) = A_i x_i(t) + B_i u_i(t), \tag{1a}$$

$$y_i(t) = C_i x_i(t), \tag{1b}$$

$i = 1,\ 2, \cdots\ N$, where $x_i(t) \in \mathbb{R}^{n_i}$, $u_i(t) \in \mathbb{R}^{r_i}$ and $y_i(t) \in \mathbb{R}^m$ are the state, control input and control output of the $i$-th agent, respectively; $A_i \in \mathbb{R}^{n_i\times n_i}$, $B_i \in \mathbb{R}^{n_i\times r_i}$, $C_i \in \mathbb{R}^{m\times n_i}$, and $\mathrm{rank} C_i = n_i$. System (1) is said to be homogeneous if $A_1 = A_2 = \ldots = A_N$, $B_1 = B_2 = \ldots = B_N$ and $C_1 = C_2 = \ldots = C_N$, otherwise, system (1) is said to be heterogeneous. Regarding the above $N$ agents as vertices, the topology relationship among them can be conveniently described by a digraph $\mathcal{G} = (\mathcal{V}, \mathcal{E}, \mathcal{A})$ with $\mathcal{V} = \{1, 2, \cdots, N\}$ and $\mathcal{A} = [a_{ij}] \in \mathbb{R}^{N\times N}$.

Comparing output feedback with state feedback, the former one would have more practical significant in consensus protocols. Because of constraints on measurement or economic costs in practice, it is sometimes hard to directly measure the relative information of all states. However, only the relative information of all outputs is available. Consensus protocols based on outputs or states are equivalent if all the states are measurable. Hence, adopt two kinds of output consensus protocols with the output feedback case as follows, respectively.

**Case One:** Since each agent has limited capability of collecting information, output consensus protocols for each agent in multi-agent systems are distributed and only depend on the information of the agent itself and its neighbors. Adopt output consensus protocols of the $i$-th agent are given by

$$u_1(t) = \sum_{j\in N_1} a_{1j} K_{1j}[y_j(t) - y_1(t)], \tag{2a}$$

$$\begin{aligned} u_i(t) =& D_i(C_1 A_1 C_1^\dagger - C_i A_i C_i^\dagger) y_i(t) \\ &+ \sum_{j\in N_i} a_{ij} K_{ij}[y_j(t) - y_i(t)], \\ & t \geq 0, i = 2, 3, \cdots, N, \end{aligned} \tag{2b}$$

where $D_i \in \mathbb{R}^{r_i\times m}$ such that $C_i B_i D_i = I$ and $K_{ij} \in \mathbb{R}^{r_i\times m}$, $i, j = 1, 2, \cdots, N$, are weighted constant matrices which will be designed.

Applying the property of $a_{ij}$, (2) is equivalent to

$$u_1(t) = \sum_{j=1}^{N} a_{1j} K_{1j}[y_j(t) - y_1(t)], \tag{3a}$$

$$\begin{aligned} u_i(t) =& D_i(C_1 A_1 C_1^\dagger - C_i A_i C_i^\dagger) y_i(t) \\ &+ \sum_{j=1}^{N} a_{ij} K_{ij}[y_j(t) - y_i(t)], \\ & t \geq 0, i = 2, 3, \cdots, N. \end{aligned} \tag{3b}$$

Let

$$u(t) = [u_1^T(t)\ u_2^T(t)\ \cdots\ u_N^T(t)]^T.$$

Define an admissible control set:

$$\begin{aligned} \mathcal{U}_1 =& \{u(t) : [0, \infty) \to \mathbb{R}^{rN} | u_1(t) = \sum_{j=1}^{N} a_{1j} K_{1j}[y_j(t) \\ & - y_1(t)],\ u_i(t) = D_i(C_1 A_1 C_1^\dagger - C_i A_i C_i^\dagger) y_i(t) \\ & + \sum_{j=1}^{N} a_{ij} K_{ij}[y_j(t) - y_i(t)], \\ & i = 2, 3, \cdots, N,\ t \geq 0,\ K_{ij} \in \mathbb{R}^{r\times m}, \\ & i, j = 1, 2, \cdots, N\}. \end{aligned}$$

**Case Two:** Adopt output consensus protocols of the $i$-th agent are given by

$$\begin{aligned} u_i(t) = \sum_{j\in N_i} a_{ij} K_{ij}[y_j(t) - y_i(t)], \\ t \geq 0, i = 1, 2, \cdots, N, \end{aligned} \tag{4}$$

where $K_{ij} \in \mathbb{R}^{r_i\times m}$, $i, j = 1, 2, \cdots, N$, are weighted constant matrices which will be designed.

Similar to Case One, define the following admissible control set:

$$\begin{aligned} \mathcal{U}_2 =& \{u(t) : [0, \infty) \to \mathbb{R}^{rN} | u_i(t) = \sum_{j=1}^{N} a_{ij} K_{ij}[y_j(t) \\ & - y_i(t)],\ i = 1, 2, \cdots, N, t \geq 0,\ K_{ij} \in \mathbb{R}^{r\times m}, \\ & i, j = 1, 2, \cdots, N\}. \end{aligned}$$

The admissible control set $\mathcal{U}_k (k = 1, 2)$ covers a relatively large class of distributed output consensus protocols. Therefore, we want to know under what conditions, the multi-agent system consisting of homogeneous or heterogeneous linear time-invariant systems is output consensusable with respect to such a kind of admissible control set. To solve this problem, a definition of the output consensusability of a multi-agent system with respect to an admissible control set $\mathcal{U}_k (k = 1, 2)$ is given as follows.

**Definition** *2.2:* For linear multi-agent system (1), if there exists a $u(t) \in \mathcal{U}_1$ ($\mathcal{U}_2$) such that for any initial value $x_i(0)$,

$$\lim_{t\to\infty} \|y_j(t) - y_i(t)\| = 0,\ i, j = 1, 2, \cdots, N,$$

then the system (1) is said to be output consensusable with respect to $\mathcal{U}_1$ ($\mathcal{U}_2$).

**Remark** *2.1:* Due to heterogeneity of the agents, to achieve the state consensus (i.e., $\lim\limits_{t\to\infty} \|x_j(t) - x_i(t)\| = 0$) is impossible generally.

**Remark** *2.2:* If $A_1 = A_i$ in the output consensus protocols (3), it is not necessary to assume that $C_iB_iD_i = I$.

**Remark** *2.3:* Definition 2.2 is different from the state consensus definition in [22], where the states of all the agents are required to converge to the same one constant value. Similar to [20], here only the output differences between different agents are required to tend to zero, no matter whether the outputs themselves converge or not.

**Remark** *2.4:* When $\sigma(A_i) \subseteq \mathbb{C}^-,\ i = 1, 2, \cdots, N$, take $K_{i,j} = 0,\ i, j = 1, 2, \cdots, N$ in output consensus protocols (3) or (4). Then it follows that $y_i,\ i = 1, 2, \cdots, N$, converges to zero exponentially. Hence multi-agent system (1) is naturally output consensusable with respect to $\mathcal{U}_k (k = 1, 2)$. Thus, assume that the eigenvalues of the matrices $A_i,\ i = 1, 2, \cdots, N$ are not all in the open left-half plane in this paper.

## III. Output Consensusability Conditions for Linear Multi-agent Systems

**Lemma** *3.1:* [23]For $A, B \in \mathbb{R}^{n\times n}$, if $(A, B)$ is stabilizable, then Riccati equation

$$A^TP + PA - PBB^TP + I_n = 0$$

has a unique nonnegative definite solution $P$, furthermore, $\sigma(A - BB^TP) \subseteq \mathbb{C}^-$.

**Theorem** *3.1:* System (1) is output consensusable with respect to $\mathcal{U}_1$ if the following conditions hold:

(i) $(C_1A_1C_1^\dagger,\ C_1B_1 + C_2B_2)$ and $(C_1A_1C_1^\dagger,\ C_iB_i)$, $i = 3, 4, \cdots, N$, are stabilizable;

(ii) $a_{12} \neq 0$, $a_{21} \neq 0$ and there exists at least one $j \in \{1, 2, \cdots, i-1\}$ such that $a_{ij} \neq 0,\ i = 3, 4, \cdots N$.

*Proof:*

Using Definition 2.2, system (1) is output consensusable with respect to $\mathcal{U}_1$ if and only if there exist matrices $K_{ij} \in \mathbb{R}^{r\times m}$ $i, j = 1, 2, \cdots N$, and output consensus protocols (3) such that for any $i \neq j$,

$$\lim_{t\to\infty} \|y_j(t) - y_i(t)\| = 0.$$

Combining (1a) and (1b) with $\mathrm{rank} C_i = n_i$, it follows that

$$\begin{aligned} \dot{y}_i(t) &= C_i\dot{x}_i(t) \\ &= C_iA_iC_i^\dagger C_ix_i(t) + C_iB_iu_i(t) \\ &= C_iA_iC_i^\dagger y_i(t) + C_iB_iu_i(t). \end{aligned} \tag{5}$$

Then output consensusability of system (1) is equivalent to state consensusability of system (5) with respect to $\mathcal{U}_1$, which implies there exist matrices $K_{ij} \in \mathbb{R}^{r\times m}$ $i, j = 1, 2, \cdots N$, and output consensus protocols (3) such that for any $i \neq j$,

$$\lim_{t\to\infty} \|y_j(t) - y_i(t)\| = 0 \tag{6}$$

for system (5).

Let $\delta_i(t) \triangleq y_1(t) - y_i(t),\ i = 2, 3, \cdots, N$. One obtains (6) is equivalent to $\lim\limits_{t\to\infty} \|\delta_i(t)\| = 0,\ i = 2, 3, \cdots, N$.

Notice that

$$\begin{aligned} \dot{\delta}_i(t) =& C_1A_1C_1^\dagger\delta_i(t) - C_1B_1\sum_{j=1}^N a_{1j}K_{1j}\delta_j(t) \\ &+ C_iB_i\sum_{j=1}^N a_{ij}K_{ij}[\delta_j(t) - \delta_i(t)] \\ =& (C_1A_1C_1^\dagger - C_iB_i\sum_{j=1}^N a_{ij}K_{ij})\delta_i(t) \\ &+ \sum_{j=1}^N (C_iB_ia_{ij}K_{ij} - C_1B_1a_{1j}K_{1j})\delta_j(t) \end{aligned}$$

$i = 2, 3, \cdots, N$. Let

$$\delta(t) = [\delta_2^T(t)\ \delta_3^T(t)\ \cdots\ \delta_N^T(t)]^T.$$

One obtains

$$\dot{\delta}(t) = \bar{A}\delta(t), \tag{7}$$

where

$$\bar{A} = \begin{pmatrix} \bar{A}_{22} & \bar{A}_{23} & \cdots & \bar{A}_{2N} \\ \bar{A}_{32} & \bar{A}_{33} & \ddots & \vdots \\ \vdots & \ddots & \ddots & \bar{A}_{(N-1)N} \\ \bar{A}_{N2} & \cdots & \bar{A}_{N(N-1)} & \bar{A}_{NN} \end{pmatrix},$$

$$
\begin{aligned}
&\bar{A}_{22} = C_1A_1C_1^{\dagger} - C_2B_2(\sum_{j=1}^{N} a_{2j}K_{2j}) - a_{12}C_1B_1K_{12},\\
&\bar{A}_{23} = a_{23}C_2B_2K_{23} - a_{13}C_1B_1K_{13},\\
&\bar{A}_{2N} = a_{2N}C_2B_2K_{2N} - a_{1N}C_1B_1K_{1N},\\
&\bar{A}_{32} = a_{32}C_3B_3K_{32} - a_{12}C_1B_1K_{12},\\
&\bar{A}_{33} = A_1 - C_3B_3(\sum_{j=1}^{N} a_{3j}K_{3j}) - a_{13}C_1B_1K_{13},\\
&\bar{A}_{(N-1)N} = a_{(N-1)N}C_{N-1}B_{N-1}K_{(N-1)N}\\
&\qquad - a_{1N}C_1B_1K_{1N},\\
&\bar{A}_{N2} = a_{N2}C_NB_NK_{N2} - a_{12}C_1B_1K_{12},\\
&\bar{A}_{N(N-1)} = a_{N(N-1)}C_NB_NK_{N(N-1)}\\
&\qquad - a_{1(N-1)}C_1B_1K_{1(N-1)},\\
&\bar{A}_{NN} = C_1A_1C_1^{\dagger} - C_NB_N(\sum_{j=1}^{N} a_{Nj}K_{Nj})\\
&\qquad - a_{1N}C_1B_1K_{1N}.
\end{aligned}
$$

In order to prove that the system (1) is output consensusable with respect to $\mathcal{U}_1$, it suffices to show that there exist matrices $K_{ij},\ i,j = 1,2,\cdots,N$, such that system (7) is stable which is equivalent to $\sigma(\bar{A}) \subseteq \mathbb{C}^-$.

In output consensus protocols (3), choose

$$K_{11} = K_{13} = K_{14}\cdots = K_{1N} = 0,$$

$$K_{ij} = 0,\ j \geq i,\ i = 2,3,\cdots,N.$$

Then $\bar{A}$ turns into

$$\bar{A} = \begin{pmatrix} \tilde{A}_{22} & 0 & \cdots & 0 \\ \tilde{A}_{32} & \tilde{A}_{33} & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ \tilde{A}_{N2} & \cdots & \tilde{A}_{N(N-1)} & \tilde{A}_{NN} \end{pmatrix},$$

where

$$
\begin{aligned}
&\tilde{A}_{22} = C_1A_1C_1^{\dagger} - a_{21}C_2B_2K_{21} - a_{12}C_1B_1K_{12},\\
&\tilde{A}_{32} = a_{32}C_3B_3K_{32} - a_{12}C_1B_1K_{12},\\
&\tilde{A}_{33} = C_1A_1C_1^{\dagger} - C_3B_3(a_{31}K_{31} + a_{32}K_{32}),\\
&\tilde{A}_{N2} = a_{N2}C_NB_NK_{N2} - a_{12}C_1B_1K_{12},\\
&\tilde{A}_{N(N-1)} = a_{N(N-1)}C_NB_NK_{N(N-1)},\\
&\tilde{A}_{NN} = C_1A_1C_1^{\dagger} - C_NB_N(\sum_{j=1}^{N-1} a_{Nj}K_{Nj}).
\end{aligned}
$$

In this case, system (7) is stable if and only if there exist $K_{12}$ and $K_{ij},\ j < i$ such that

$$\sigma\left(C_1A_1C_1^{\dagger} - a_{21}C_2B_2K_{21} - a_{12}C_1B_1K_{12}\right) \subseteq \mathbb{C}^-,$$

$$\sigma\left(C_1A_1C_1^{\dagger} - C_iB_i(\sum_{j=1}^{i-1} a_{ij}K_{ij})\right) \subseteq \mathbb{C}^-,\ i = 3,4\cdots,N.$$

Since condition (ii) holds, it is concluded from Lemma 3.1 that

$$
\begin{aligned}
&(C_1A_1C_1^{\dagger})^TX + X^T(C_1A_1C_1^{\dagger})\\
&\quad - X^T(C_1B_1 + C_2B_2)(C_1B_1 + C_2B_2)^TX + I_n = 0
\end{aligned}
\tag{8}
$$

has the unique admissible solution $P_2$ and

$$
\begin{aligned}
&(C_1A_1C_1^{\dagger})^TX_i + X_i^T(C_1A_1C_1^{\dagger})\\
&\quad - X_i^TC_iB_i(C_iB_i)^TX_i + I_n = 0
\end{aligned}
\tag{9}
$$

has the unique admissible solution $P_i,\ i = 3,4,\cdots,N$. Hence

$$\sigma\left(C_1A_1C_1^{\dagger} - (C_1B_1 + C_2B_2)(C_1B_1 + C_2B_2)^TP_2\right) \subseteq \mathbb{C}^-,$$

$$\sigma\left(C_1A_1C_1^{\dagger} - C_iB_i(C_iB_i)^TP_i\right) \subseteq \mathbb{C}^-,\ i = 3,4,\cdots,N.$$

Let

$$a_{12}K_{12} = a_{21}K_{21} = (C_1B_1 + C_2B_2)^TP_2 \tag{10}$$

and

$$\sum_{j=1}^{i-1} a_{ij}K_{ij} = (C_iB_i)^TP_i,\ i = 3,4,\cdots,N. \tag{11}$$

Under the condition (iii), it is obtained that equations (10) and (11) have at least one group solutions $K_{12}$ and $K_{ij},\ j < i,\ i = 2,3,\cdots,N$, such that

$$\sigma\left(C_1A_1C_1^{\dagger} - a_{21}C_2B_2K_{21} - a_{12}C_1B_1K_{12}\right) \subseteq \mathbb{C}^-,$$

$$\sigma\left(C_1A_1C_1^{\dagger} - C_iB_i(\sum_{j=1}^{i-1} a_{ij}K_{ij})\right) \subseteq \mathbb{C}^-,\ i = 3,4\cdots,N.$$

Combining the above results, one obtains multi-agent system (1) is output consensusable with respect to $\mathcal{U}_1$. ■

**Theorem** *3.2:* System (1) is output consensusable with respect to $\mathcal{U}_2$ if the following conditions hold:

(i) $C_1A_1C_1^{\dagger} = C_2A_2C_2^{\dagger} = \cdots = C_NA_NC_N^{\dagger}$;

(ii) $(C_1A_1C_1^{\dagger},\ C_1B_1 + C_2B_2)$ and $(C_1A_1C_1^{\dagger},\ C_iB_i)$, $i = 3,4,\cdots,N$, are stabilizable;

(iii) $a_{12} \neq 0$, $a_{21} \neq 0$ and there exists at least one $j \in \{1,2,\cdots,i-1\}$ such that $a_{ij} \neq 0,\ i = 3,4,\cdots N$.

*Proof:* Here, this proof is omitted since it is very similar to that of Theorem 3.1. ■

Based on Theorem 3.1, give the following algorithm to design the output feedback control law $K_{ij},\ i,j = 1,2,\cdots N$, which can guarantee that system (1) is output consensusable with respect to $\mathcal{U}_1$ under the precondition of Theorem 3.1.

**Algorithm** *3.1:* Input: the matrices $A_i \in \mathbb{R}^{n_i\times n_i}$, $B_i \in \mathbb{R}^{n_i\times r_i}$, $C_i \in \mathbb{R}^{m\times n_i}$, $i = 1,2,\cdots,N$, and $\mathcal{A} = [a_{ij}] \in \mathbb{R}^{N\times N}$;

Output: the gain matrix $K_{ij},\ i,j = 1,2,\cdots,N$.

(a) Compute Moore-Penrose inverse of $C_i$, and it is denoted by $C_i^{\dagger},\ i = 1,2,\cdots,N$;

(b) Solve Ricatti equations (8) and (9), and the admissible solutions are denoted by $P_2$ and $P_i,\ i = 3,4,\cdots,N$, respectively;

(c) Choose $K_{11} = K_{13} = K_{14} \cdots = K_{1N} = 0,\ K_{ij} = 0,\ j \geq i,\ i = 2, 3, \cdots, N$;

(d) Solve an arbitrary group of solutions of matrix equations (10) and (11), and denote them by $K_{12}$ and $K_{ij},\ j < i,\ i = 2, 3, \cdots, N$, respectively.

Thus, the required matrices $K_{ij},\ i, j = 1, 2, 3$, are designed.

## IV. A Numerical Example

A numerical example is provided to demonstrate the application of Algorithm 3.1. Consider linear multi-agent system (1) consisting of $N = 3$ heterogeneous agents with

$$A_1 = \begin{bmatrix} -2 & 0.5 \\ 1 & -1 \end{bmatrix},\ A_2 = \begin{bmatrix} 0.5 & 0 \\ -1 & 1 \end{bmatrix},$$

$$A_3 = \begin{bmatrix} 0 & 1 \\ -2 & 1 \end{bmatrix},\ B_1 = \begin{bmatrix} 0.6 & 1 \\ -5 & 1 \end{bmatrix},$$

$$B_2 = \begin{bmatrix} 4 & 1.5 \\ -1 & 0.9 \end{bmatrix},\ B_3 = \begin{bmatrix} 0.3 & -1 \\ 2 & 5 \end{bmatrix},$$

$$C_1 = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix},\ C_2 = \begin{bmatrix} 1 & -1 \\ 0 & 1 \end{bmatrix},\ C_3 = \begin{bmatrix} 1 & 3 \\ 1 & 2 \end{bmatrix},$$

and the topology $\mathcal{G} = (\mathcal{V}, \mathcal{E}, \mathcal{A})$, where $\mathcal{V} = \{1, 2, 3\}$,

$$\mathcal{E} = \{(1, 2),\ (1, 3),\ (2, 1),\ (2, 3),\ (3, 1),\ (3, 2)\}$$

and

$$\mathcal{A} = \begin{bmatrix} 0 & 0.5 & 2 \\ 0.2 & 0 & 3 \\ 1 & 0.4 & 0 \end{bmatrix}.$$

According to the steps in Algorithm 3.1, the following can be obtained:

(a)

$$C_1^{\dagger} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix},\ C_2^{\dagger} = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix},$$

$$C_3^{\dagger} = \begin{bmatrix} -2 & 3 \\ 1 & -1 \end{bmatrix};$$

(b)

$$P_2 = \begin{bmatrix} 0.2 & 0.1 \\ 0.1 & 0.2 \end{bmatrix},\ P_3 = \begin{bmatrix} 0.1 & 0.1 \\ -0.1 & 0.2 \end{bmatrix};$$

(c)

$$K_{11} = K_{13} = K_{22} = K_{23} = K_{33} = 0_{n \times n};$$

(d)

$$K_{12} = \begin{bmatrix} 0.9 & -1.3 \\ 1.0 & 1.1 \end{bmatrix},\ K_{21} = \begin{bmatrix} 2.2 & -3.2 \\ 2.5 & 2.7 \end{bmatrix},$$

$$K_{31} = \begin{bmatrix} 0.7 & 1 \\ -1 & 2 \end{bmatrix},\ K_{32} = \begin{bmatrix} -1.1 & -1.7 \\ 4.1 & -3.4 \end{bmatrix}.$$

Then the matrices $K_{ij},\ i, j = 1, 2, 3$, are designed.

In this case, the closed-loop system made of (1) and (2) is formulated:

$$\dot{x}(t) = A_c x(t), \tag{12a}$$

$$y(t) = Cx(t), \tag{12b}$$

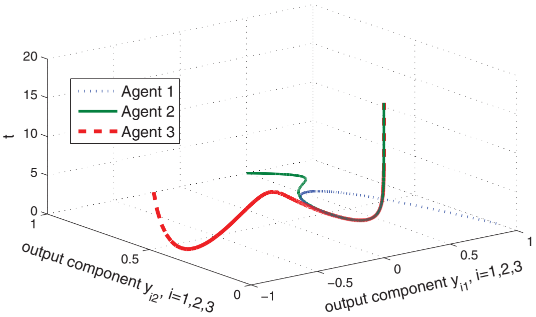

Fig. 1. the output responses of system (12)

where

$$A_c = \begin{bmatrix} A_{11} & a_{12}B_1K_{12}C_2 & a_{13}B_1K_{13}C_3 \\ a_{21}B_2K_{21}C_1 & A_{22} & a_{31}B_2K_{31}C_3 \\ a_{31}B_3K_{31}C_1 & a_{32}B_3K_{32}C_2 & A_{33} \end{bmatrix},$$

$$x = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix},\ y = \begin{bmatrix} y_1 \\ y_2 \\ y_3 \end{bmatrix},\ C = \begin{bmatrix} C_1 & 0 & 0 \\ 0 & C_2 & 0 \\ 0 & 0 & C_3 \end{bmatrix},$$

$$A_{11} = A_1 - a_{12}B_1K_{12}C_1 - a_{13}B_1K_{13}C_1,$$

$$A_{22} = B_2D_2C_1A_1C_1^{\dagger}C_2 - a_{21}B_2K_{21}C_2 - a_{31}B_2K_{31}C_2,$$

$$A_{33} = B_3D_3C_1A_1C_1^{\dagger}C_3 - a_{31}B_3K_{31}C_3 - a_{32}B_3K_{32}C_3.$$

Choose the initial states of system (1) arbitrarily as follows:

$$x_1(0) = \begin{bmatrix} 1 \\ 0.1 \end{bmatrix},\ x_2(0) = \begin{bmatrix} 1.5 \\ 1 \end{bmatrix},\ x_3(0) = \begin{bmatrix} 3.4 \\ -1.2 \end{bmatrix}.$$

Denote

$$y_i = \begin{bmatrix} y_{i1} \\ y_{i2} \end{bmatrix},\ i = 1, 2, 3.$$

The simulation of system (12) is presented in Figure 1. It shows that the output responses of the system (12) indicates multi-agent system (1) is output consensusable with respect to the given admissible set $\mathcal{U}_1$.

## V. Conclusion

For linear multi-agent systems with fixed topologies and agents consisting of general linear systems, the conditions of output consensusability have been provided using generalized inverse, graph and linear system theory. The designed output feedback control law can guarantee that the studied multi-agent systems are output consensusable with respect to a given admissible set. Moreover, the simulation results have successfully demonstrated the applicability of the proposed approach in this paper.

The study of output consensus conditions for linear multi-agent systems with fixed topologies is a basic problem which only serves as a stepping stone to study more complicated agent dynamics. Future research will be on multi-agent systems with time delays, switching topology or time-varying topology, and so on.

***Abstract*—The consensusability problem of discrete-time linear networked multi-agent systems with a communication delay is investigated in this paper. Based on the networked predictive control scheme and dynamic output feedback control, a novel protocol is proposed to compensate for communication delay actively. For discrete-time linear networked multi-agent systems with a directed topology and a constant network delay, necessary and/or sufficient conditions of consensusability with respect to a set of admissible consensus protocols are given. A simulation result demonstrates the effectiveness of theoretical results.**

***Index Terms*—Consensusability, networked multi-agent systems, networked predictive control.**

## I. Introduction

Recently, consensus problem has received significant attention as a fundamental research topic in decentralized control of networks of dynamic agents, due to its broad applications in cooperative control of unmanned aerial vehicles, scheduling of automated highway systems, formation control of satellite clusters, distributed optimization of multiple robotic systems, etc.

The most of existing works [1] about consensus problems focused on how consensus protocols are designed to achieve good performances. However, the consensusability problem of networked multi-agent systems is lack of enough attention, which is concerned about the existence of consensus protocols, and important in both synthesis and implementation of the protocols [2], [3].

Since the communication among agents in the networked multi-agent systems (NMASs) is achieved by a network, it is inevitable that the network-induced delay will occur while exchanging data among devices connected to the shared network, due to the limited bandwidth of the communication channels and the finite transmission speed. However, time delay can degrade the performance of control systems and even destabilize the system [4], [5]. Besides, due to economic costs or constraints on measurement in practice, it is often difficult or even unavailable to get the information of all the agents' states. Therefore, the consensusability problem of discrete-time linear networked multi-agent systems with a communication delay is investigated in this paper. By exploiting the networked predictive control scheme proposed by Liu [6], [7], a novel distributed protocol is put forward to overcome the effect of network delay actively rather than passively. For the NMAS consisting of uniform discrete-time linear time-invariant dynamical nodes with a directed topology and a constant network delay, delay-independent necessary and/or sufficient conditions of consensusability with respect to a set of admissible consensus protocols are established.

The paper is organized as follows. Some preliminaries of graph theory are briefly reviewed in Section II. Main results are given in Section III. To illustrate the theoretical results, a numerical simulation is provided in Section IV. Finally, Section V concludes the paper.

## II. Preliminaries

In this context, some necessary notations are introduced to make readers to easily understand. Let $\mathbb{R}$ and $\mathbb{C}$ be real and complex number fields, respectively. $M_{m,n}(\mathbb{F})$ denotes the set of all $m$-by-$n$ matrices over a field $\mathbb{F}$, and $M_{n,n}(\mathbb{F})$ is abbreviated to $M_n(\mathbb{F})$. For $A \in M_{m,n}(\mathbb{C})$, $A^{\mathrm{T}}$ denotes the transpose of $A$. Specially $m = n$, $A$ is said to be Schur if $\sigma(A) \subseteq U_0$, where $\sigma(A)$ represents the spectrum of matrix $A$, and $U_0$ denotes an open unit disk centered at the origin. $\otimes$ stands for the Kronecker product of matrices. $\mathbf{1}_N$ denotes a $N$-dimension column vector with all entries equal to one. 0 represents zero matrix with an appropriate dimension. $\|\cdot\|$ represents $l^2$ norm on vectors or its induced norm on matrices. "With respect to" is short for w.r.t..

First of all, some basic concepts and notations in graph theory are briefly introduce, which is very important and helpful in the analysis of NMASs. Let $\mathcal{G} = (\mathcal{V}, \mathcal{E}, \mathcal{A})$ be a weighted digraph of order $N$, where the set of nodes $\mathcal{V} = \{1, 2, \cdots, N\}$, set of edges $\mathcal{E} \subseteq \mathcal{V} \times \mathcal{V}$, and a nonnegative weighted adjacency matrix $\mathcal{A} = [a_{ij}] \in M_N(\mathbb{R})$. An edge from $i$ to $j$ is denoted by $e_{ij} = (i, j)$ and adjacency element $a_{ji}$ associated with edge $e_{ij}$ is positive, i.e., $e_{ij} \in \mathcal{E} \Leftrightarrow a_{ji} > 0$. Moreover, assume that $a_{ii} = 0$ for all $i \in \mathcal{V}$. The set of neighbors of the node $i$ is denoted by $N_i = \{j \in \mathcal{V} : (j, i) \in \mathcal{E}\}$. The set of all reachable nodes to node $i$ is denoted by $N_i^*$. The Laplacian matrix $\mathcal{L} = [l_{ij}]_{n \times n}$ of weighted digraph $\mathcal{G}$ is defined as $\mathcal{L} = \mathcal{D} - \mathcal{A}$, where $\mathcal{D} = \mathrm{diag}(d_{in}(1), d_{in}(2), \cdots, d_{in}(N))$ and $d_{in}(i) = \sum\limits_{j=1, j \neq i}^{N} a_{ij}$, $i = 1, 2, \cdots, N$. Obviously, all the row-sums of $\mathcal{L}$ are zero, which implies that $\mathcal{L}$ has always an eigenvalue zero corresponding the right eigenvector $\mathbf{1}_N$. For a comprehensive restatement of the graph theory, the reader is referred to [8].

## III. Consensusability Based on the Networked Predictive Control Scheme

Consider an NMAS composed of $N$ agents, where the dynamics of agent $i$ are described by a discrete-time linear time-invariant system as follows:

$$\begin{aligned} x_i(t+1) = &\ Ax_i(t) + B_i u_i(t), \\ y_i(t) = &\ Cx_i(t), \\ i = &\ 1, 2, \cdots, N, \ t = 0, 1, 2, \cdots, \end{aligned} \tag{1}$$

where $x_i \in M_{n,1}(\mathbb{R})$, $u_i \in M_{m,1}(\mathbb{R})$ and $y_i \in M_{l,1}(\mathbb{R})$ are the state, control input and measured output of the agent $i$, respectively. $A \in M_n(\mathbb{R})$, $B_i \in M_{n,m}(\mathbb{R})$, $C \in M_{l,n}(\mathbb{R})$ are constant matrices.

Regarding the above $N$ agents as nodes of a graph, the communication relationship among agents can be conveniently represented by a weighted digraph $\mathcal{G} = (\mathcal{V}, \mathcal{E}, \mathcal{A})$ with the set of nodes $\mathcal{V} = \{1, 2, \cdots, N\}$, set of edges $\mathcal{E} \subseteq \mathcal{V} \times \mathcal{V}$, and a nonnegative weighted adjacency matrix $\mathcal{A}$. The directed edge $e_{ij} \in \mathcal{E}$ means that agent $j$ can receive the information from agent $i$.

In this paper, it is considered that the information exchanged among all agents is achieved by a network with a time delay $\tau$. And the following assumptions can reasonably be made:

*Assumption 1:* (A1) Network delay $\tau$ is a constant and known positive integer.

(A2) States of all agents are not available but the outputs of them can be measured.

(A3) Each agent can receive information from itself and all reachable nodes to it, i.e. for $\forall j \in \{i\} \cup N_i^*$, agent $i$ can receive information from agent $j$, where $i \in \mathcal{V}$.

Because agent $i$ receives the information from agent $j$ ($j \in \{i\} \cup N_i^*$) with time delay $\tau$, in order to overcome the effect of the network delay, based on the output data of agent $j$ up to time $t - \tau$, the state predictions of agent $j$ from time $t - \tau$ to $t$ are constructed as:

$$\begin{aligned} \hat{x}_j(t-\tau+1|t-\tau) = &\ A\hat{x}_j(t-\tau|t-\tau-1) \\ &+ B_j u_j(t-\tau) + G_j\left[y_j(t-\tau)\right. \\ &\left.- C\hat{x}_j(t-\tau|t-\tau-1)\right], \end{aligned} \tag{2a}$$

$$\begin{aligned} \hat{x}_j(t-\tau+2|t-\tau) = &\ A\hat{x}_j(t-\tau+1|t-\tau) \\ &+ B_j u_j(t-\tau+1), \\ \hat{x}_j(t-\tau+3|t-\tau) = &\ A\hat{x}_j(t-\tau+2|t-\tau) \\ &+ B_j u_j(t-\tau+2), \\ &\vdots \\ \hat{x}_j(t|t-\tau) = &\ A\hat{x}_j(t-1|t-\tau) + B_j u_j(t-1), \\ &\ j \in \{i\} \cup N_i^*, \end{aligned} \tag{2b}$$

where $\hat{x}_j(t-\tau+1|t-\tau) \in M_{n,1}(\mathbb{R})$ and $u_j(t-\tau) \in M_{m,1}(\mathbb{R})$ are the one-step ahead state prediction and the input of the observer at time $t - \tau$, respectively, and $G_j \in M_{n,l}(\mathbb{R})$ can be designed using observer design approaches, $\hat{x}_j(t-\tau+d|t-\tau) \in M_{n,1}(\mathbb{R})$ is a state prediction of agent $j$ at time $t - \tau + d$ on the basis of information up to time $t - \tau$, and $u_j(t-\tau+d-1) \in M_{m,1}(\mathbb{R})$ is the input at time $t-\tau+d-1$, $d = 2, 3, \cdots, \tau$, $j \in \{i\} \cup N_i^*$.

For agent $i$ of NMAS (1), the following protocol based on the dynamic output feedback is designed:

$$\begin{aligned} z_i(t+1) &= \hat{A}_i z_i(t) + \hat{H}_i \zeta_i(t|t-\tau), \\ u_i(t) &= \hat{C}_i z_i(t) + \hat{F}_i \zeta_i(t|t-\tau), \\ i &= 1, 2, \cdots, N, \ t = 0, 1, 2, \cdots, \end{aligned} \tag{3}$$

where $z_i \in M_{\tilde{n},1}(\mathbb{R})$ is the protocol state, and

$$\zeta_i(t|t-\tau) = \sum_{j \in N_i} a_{ij}(\hat{y}_j(t|t-\tau) - \hat{y}_i(t|t-\tau)) \tag{4}$$

is the weighted sum of output prediction differences between agent $i$ and its neighboring ones, $\hat{y}_i(t|t-\tau) = C\hat{x}_i(t|t-\tau)$ is the output prediction of agent $i$ at time $t$ based on the output data of agent $i$ up to time $t - \tau$. $\mathcal{A} = [a_{ij}] \in M_{\scriptscriptstyle N}(\mathbb{R})$ is the weighted adjacency matrix of digraph $\mathcal{G}$. $\hat{A}_i$, $\hat{C}_i$, $\hat{H}_i$, $\hat{F}_i$ are matrices to be designed.

Let $u(t) = \left[\begin{array}{cccc} u_1^{\mathrm{T}}(t) & u_2^{\mathrm{T}}(t) & \cdots & u_{\scriptscriptstyle N}^{\mathrm{T}}(t) \end{array}\right]^{\mathrm{T}}$. The following admissible control set is considered:

$$\begin{aligned} \mathscr{U}^* = &\ \{u(t) : [0, +\infty) \to M_{\scriptscriptstyle Nm,1}(\mathbb{R}) \,\big|\, u_i(t) \text{ satisfies} \\ &\ (3), i = 1, 2, \cdots, N\}. \end{aligned} \tag{5}$$

*Definition 1:* NMAS (1) is said to be consensusable w.r.t. $\mathscr{U}^*$, if there exists a $u(t) \in \mathscr{U}^*$ such that for any initial value $x_i(0)$, $z_i(0)$ and $e_i(t)$, $t = -\tau, -\tau+1, \cdots, -1, 0$, $i \in \mathcal{V}$, the following conditions hold:

(1) $\lim\limits_{t \to \infty} \|x_i(t) - x_j(t)\| = 0, \ \forall\, i, j \in \mathcal{V}$,

(2) $\lim\limits_{t \to \infty} z_i(t) = 0, \ \forall\, i \in \mathcal{V}$,

(3) $\lim\limits_{t \to \infty} e_i(t) = 0, \ \forall\, i \in \mathcal{V}$,

where $e_i(t) = \hat{x}_i(t|t-1) - x_i(t)$ is the estimate error satisfying

$$\begin{aligned} e_i(t+1) = (A - G_i C)e_i(t), \ i \in \mathcal{V}, \\ t = -\tau, -\tau+1, \cdots, -1, 0, 1, \cdots. \end{aligned} \tag{6}$$

Let

$$\begin{aligned} \delta_i(t) &= x_1(t) - x_i(t), \ i = 1, 2, \cdots, N, \\ \delta(t) &= \left[\begin{array}{cccc} \delta_2^{\mathrm{T}}(t) & \delta_3^{\mathrm{T}}(t) & \cdots & \delta_{\scriptscriptstyle N}^{\mathrm{T}}(t) \end{array}\right]^{\mathrm{T}}, \\ x(t) &= \left[\begin{array}{cccc} x_1^{\mathrm{T}}(t) & x_2^{\mathrm{T}}(t) & \cdots & x_{\scriptscriptstyle N}^{\mathrm{T}}(t) \end{array}\right]^{\mathrm{T}}, \\ z(t) &= \left[\begin{array}{cccc} z_1^{\mathrm{T}}(t) & z_2^{\mathrm{T}}(t) & \cdots & z_{\scriptscriptstyle N}^{\mathrm{T}}(t) \end{array}\right]^{\mathrm{T}}, \\ e(t) &= \left[\begin{array}{cccc} e_1^{\mathrm{T}}(t) & e_2^{\mathrm{T}}(t) & \cdots & e_{\scriptscriptstyle N}^{\mathrm{T}}(t) \end{array}\right]^{\mathrm{T}}. \end{aligned}$$

For NMAS (1) with a fixed and directed topology, along with a constant network delay, a necessary and sufficient condition of consensusability of NMAS (1) w.r.t. $\mathscr{U}^*$ will be presented as follows.

*Theorem 1:* Consider NMAS (1) with a directed topology $\mathcal{G} = (\mathcal{V}, \mathcal{E}, \mathcal{A})$ and a network delay $\tau$. NMAS (1) is consensusable w.r.t. $\mathscr{U}^*$ if and only if

$$(A, C) \text{ is detectable,} \tag{7}$$

and there exist $\hat{A}_i \in M_{\tilde{n}}$, $\hat{C}_i \in M_{m,\tilde{n}}$, $\hat{H}_i \in M_{\tilde{n},l}$ and $\hat{F}_i \in M_{m,l}$, $i = 1, 2, \cdots, N$, such that

$$\Theta \triangleq \begin{bmatrix} I_{N-1} \otimes A + RB_{D}\hat{F}_{D}(\mathcal{L}_2 \otimes C) & RB_{D}\hat{C}_{D} \\ \hat{H}_{D}(\mathcal{L}_2 \otimes C) & \hat{A}_{D} \end{bmatrix} \text{ is Schur,} \tag{8}$$

where $R = \begin{bmatrix} \mathbf{1}_{N-1} & -I_{N-1} \end{bmatrix} \otimes I_n$, $\mathcal{L}_2 = \mathcal{L} \begin{bmatrix} 0 & I_{N-1} \end{bmatrix}^{\mathrm{T}}$ and $\mathcal{L}$ is the Laplacian matrix of the graph $\mathcal{G}$.

*Proof:* From (2),

$$\begin{aligned} \zeta_i(t|t-\tau) = {} & C(\tilde{l}_i \otimes I_n)\delta(t) \\ & - CA^{\tau-1}(l_i \otimes I_n)e(t-\tau+1), \end{aligned} \tag{9}$$

where

$$\tilde{l}_i = \begin{bmatrix} l_{i2} & l_{i3} & \cdots & l_{iN} \end{bmatrix}$$

and

$$l_i = \begin{bmatrix} l_{i1} & \tilde{l}_i \end{bmatrix}, \ i = 1, 2, \cdots, N.$$

Substituting (9) into (3) derives

$$\begin{aligned} u_i(t) &= \hat{C}_i z_i(t) + \hat{F}_i \zeta_i(t) \\ &= \hat{C}_i z_i(t) + \hat{F}_i C(\tilde{l}_i \otimes I_n)\delta(t) \\ &\quad - \hat{F}_i CA^{\tau-1}(l_i \otimes I_n)e(t-\tau+1), \\ i &= 1, 2, \cdots, N. \end{aligned} \tag{10}$$

Hence, the closed-loop systems subjected to protocol (3) have the following forms:

$$\begin{aligned} x_i(t+1) &= Ax_i(t) + B_i u_i(t) \\ &= Ax_i(t) + B_i\hat{C}_i z_i(t) + B_i\hat{F}_i C(\tilde{l}_i \otimes I_n)\delta(t) \\ &\quad - B_i\hat{F}_i CA^{\tau-1}(l_i \otimes I_n)e(t-\tau+1) \end{aligned}$$

and

$$\begin{aligned} z_i(t+1) &= \hat{A}_i z_i(t) + \hat{H}_i \zeta_i(t) \\ &= \hat{A}_i z_i(t) + \hat{H}_i C(\tilde{l}_i \otimes I_n)\delta(t) \\ &\quad - \hat{H}_i CA^{\tau-1}(l_i \otimes I_n)e(t-\tau+1), \\ i &= 1, 2, \cdots, N. \end{aligned}$$

Then the following compact form can be presented:

$$\begin{aligned} x(t+1) &= (I_{N} \otimes A)x(t) + B_{D}\hat{C}_{D}z(t) \\ &\quad + B_{D}\hat{F}_{D}(\mathcal{L}_2 \otimes C)\delta(t) \\ &\quad - B_{D}\hat{F}_{D}[\mathcal{L} \otimes (CA^{\tau-1})]e(t-\tau+1) \end{aligned}$$

and

$$\begin{aligned} z(t+1) &= \hat{A}_{D}z(t) + \hat{H}_{D}(\mathcal{L}_2 \otimes C)\delta(t) \\ &\quad - \hat{H}_{D}[\mathcal{L} \otimes (CA^{\tau-1})]e(t-\tau+1). \end{aligned}$$

It should be noted that

$$\delta(t) = Rx(t)$$

and

$$e_i(t) = (A - G_iC)e_i(t-1), \ i = 1, 2, \cdots, N.$$

Therefore, the generalized closed-loop system can be described as

$$\xi(t+1) = \Omega\xi(t), \tag{11}$$

where

$$\begin{aligned} \xi(t) &= \begin{bmatrix} \delta^{\mathrm{T}}(t) & z^{\mathrm{T}}(t) & e^{\mathrm{T}}(t-\tau+1) \end{bmatrix}^{\mathrm{T}}, \\ \Omega &= \begin{bmatrix} \Omega_1 & RB_{D}\hat{C}_{D} & \Omega_2 \\ \hat{H}_{D}(\mathcal{L}_2 \otimes C) & \hat{A}_{D} & \Omega_3 \\ 0 & 0 & \Omega_4 \end{bmatrix}, \\ \Omega_1 &= I_{N-1} \otimes A + RB_{D}\hat{F}_{D}(\mathcal{L}_2 \otimes C), \\ \Omega_2 &= -RB_{D}\hat{F}_{D}[\mathcal{L} \otimes (CA^{\tau-1})], \\ \Omega_3 &= -\hat{H}_{D}[\mathcal{L} \otimes (CA^{\tau-1})], \\ \Omega_4 &= I_{N} \otimes A - G_{D}(I_{N} \otimes C). \end{aligned}$$

From Definition 1, NMAS (1) is consensusable w.r.t. $\mathscr{U}^*$ if and only if system (11) is asymptotically stable or, equivalently, $\Omega$ is Schur. So it follows from (7) and (8) that the conclusion holds. ■

Theorem 1 provides a necessary and sufficient condition of the consensusability of NMAS (1) w.r.t. $\mathscr{U}^*$. Based on it, a sufficient condition of the consensusability will be presented.

*Corollary 1:* Consider NMAS (1) with a directed topology $\mathcal{G} = (\mathcal{V}, \mathcal{E}, \mathcal{A})$ and a network delay $\tau$. If there exist $\hat{A}_i \in M_{\tilde{n}}$ and $\hat{F}_i \in M_{m,l}$, $i = 1, 2, \cdots, N$, satisfying that the following conditions (i) – (iii) hold, then NMAS (1) is consensusable w.r.t. $\mathscr{U}^*$.

(i) $(A, C)$ is detectable.
(ii) $\hat{A}_i$ is Schur, $i = 1, 2, \cdots, N$.
(iii) $I_{N-1} \otimes A + RB_{D}\hat{F}_{D}(\mathcal{L}_2 \otimes C)$ is Schur,

where $R$ and $\mathcal{L}_2$ are defined in Theorem 1.

*Proof:* By choosing $\hat{C}_i$ to satisfy $B_i\hat{C}_i = 0$, or choosing $\hat{H}_i$ to satisfy $\hat{H}_iC = 0$, $i = 1, 2, \cdots, N$, it is sufficient that $\hat{A}_{D}$ and $I_{N-1} \otimes A + RB_{D}\hat{F}_{D}(\mathcal{L}_2 \otimes C)$ are Schur. Hence, from Theorem 1, NMAS (1) is consensusable w.r.t. $\mathscr{U}^*$. The proof is completed. ■

## IV. Simulation

In this section, a numerical simulation is presented to illustrate the effectiveness of the proposed theoretical results.

*Example 1:* Consider an NMAS with a network delay $\tau = 3$ and four agents indexed by 1, 2, 3 and 4, respectively. The dynamics of agent $i$ ($i = 1, 2, 3, 4$) are described by (1), where

$$A = \begin{bmatrix} 1 & 1.5 & 0.6 \\ -0.5 & -0.8 & 0.5 \\ 0 & 0.65 & 0.05 \end{bmatrix},$$

$$C = \begin{bmatrix} 1 & -1 & 1 \\ 2 & 1 & -1 \\ 1 & 1 & 1 \end{bmatrix},$$

$$B_1 = B_2 = B_3 = B_4 = \begin{bmatrix} 1 & 0 \\ -1 & 0 \\ 1 & 0 \end{bmatrix}.$$

The interconnection among four agents is described by $\mathcal{G}$ in Fig. 1 with the adjacent matrix

$$\mathcal{A} = \begin{bmatrix} 0 & 1 & 1 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix}.$$

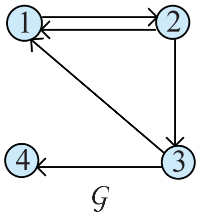

Fig. 1. Fixed topology.

It is obvious that $(A, C)$ is detectable. By choosing $Q = 6I_3$ and using MATLAB, a solution of Riccati equation

$$APA^{\mathrm{T}} - P - APC^{\mathrm{T}}(I + CPC^{\mathrm{T}})^{-1}CPA^{\mathrm{T}} + Q = 0$$

can be obtained as:

$$P = \begin{bmatrix} 7.1235 & -0.2844 & 0.4230 \\ -0.2844 & 6.2245 & -0.1377 \\ 0.4230 & -0.1377 & 6.2029 \end{bmatrix}.$$

Then a gain matrix of the observer (2a) can be got

$$G = \begin{bmatrix} -0.2752 & 0.1567 & 0.9671 \\ 0.2981 & -0.3275 & -0.1394 \\ -0.2913 & -0.0057 & 0.3157 \end{bmatrix}.$$

Take

$$\hat{A}_1 = \begin{bmatrix} -0.2 & 0 & 0 \\ 0 & 0.6 & 0 \\ 0 & 0 & 0.5 \end{bmatrix}, \ \hat{A}_2 = \begin{bmatrix} -0.3 & 0 & 0 \\ 0 & 0.8 & 0 \\ 0 & 0 & 0.1 \end{bmatrix},$$

$$\hat{A}_3 = \begin{bmatrix} 0.1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0.3 \end{bmatrix}, \ \hat{A}_4 = \begin{bmatrix} -0.5 & 0 & 0 \\ 0 & 0.2 & 0 \\ 0 & 0 & 0.85 \end{bmatrix},$$

$$\hat{C}_1 = \begin{bmatrix} 0 & 0 & 0 \\ 1 & 4 & 1 \end{bmatrix}, \ \hat{C}_2 = \begin{bmatrix} 0 & 0 & 0 \\ 1 & 1 & 2 \end{bmatrix},$$

$$\hat{C}_3 = \begin{bmatrix} 0 & 0 & 0 \\ 1 & 2 & 1 \end{bmatrix}, \ \hat{C}_4 = \begin{bmatrix} 0 & 0 & 0 \\ 0.5 & -2 & 1 \end{bmatrix},$$

$$\hat{H}_1 = \begin{bmatrix} -1.4980 & -1.2360 & 2.3740 \\ -3.2956 & -2.7192 & 5.2228 \\ 1.4980 & 1.2360 & -2.3740 \end{bmatrix},$$

$$\hat{H}_2 = \begin{bmatrix} 1.4980 & 1.2360 & -2.3740 \\ -2.3519 & -1.9405 & 3.7272 \\ -4.4940 & -3.7080 & 7.1220 \end{bmatrix},$$

$$\hat{H}_3 = \begin{bmatrix} -0.4494 & -0.3708 & 0.7122 \\ 0 & 0 & 0 \\ -1.4980 & -1.2360 & 2.3740 \end{bmatrix},$$

$$\hat{H}_4 = \begin{bmatrix} 0 & 0 & 0 \\ 3.5203 & 2.9046 & -5.5789 \\ -1.4980 & -1.2360 & 2.3740 \end{bmatrix},$$

$$\hat{F}_1 = \begin{bmatrix} -0.0997 & 0.0449 & -0.1473 \\ -0.1898 & 0.0896 & 0.0370 \end{bmatrix},$$

$$\hat{F}_2 = \begin{bmatrix} -0.0806 & 0.0453 & -0.1508 \\ -0.2257 & 0.1075 & 0.0389 \end{bmatrix},$$

$$\hat{F}_3 = \begin{bmatrix} -0.0935 & 0.0532 & -0.1715 \\ -0.0332 & 0.0140 & 0.2052 \end{bmatrix},$$

$$\hat{F}_4 = \begin{bmatrix} -0.3333 & 0.0667 & 0.4000 \\ 0.8333 & 0.3333 & -0.5000 \end{bmatrix}.$$

It is easy to verify that

$$\sigma(\Theta) = \{0.2, 0.6, 0.5, 0.3, 0.8, 0.1, 0.1, 0.2, 0.3, 0.85, \\ 0.3803, 0.2861, 0.0705, 0.6245, 0.6245, 0.8272, \\ 0.8272, 0.7703, 0.7703, 0, 0.5\} \subseteq U_0.$$

Hence, NMAS (1) is consensusable w.r.t. $\mathscr{U}^*$ by Theorem 1.

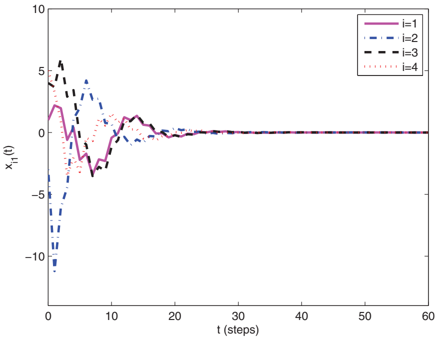

Fig. 2. Trajectories of the first state variables.

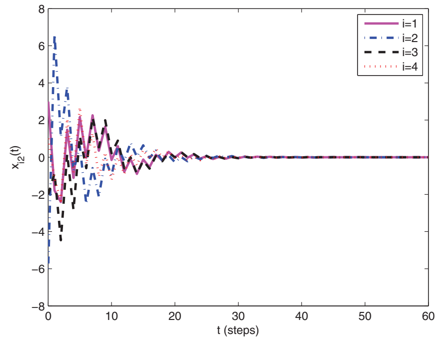

Fig. 3. Trajectories of the second state variables.

Initial conditions of NMAS (1), protocol (3) are chosen as

$$x_1(0) = \begin{bmatrix} 1 & 3 & -2 \end{bmatrix}^{\mathrm{T}}, \quad x_2(0) = \begin{bmatrix} -3 & -6 & 1 \end{bmatrix}^{\mathrm{T}},$$
$$x_3(0) = \begin{bmatrix} 4 & -2 & 2 \end{bmatrix}^{\mathrm{T}}, \quad x_4(0) = \begin{bmatrix} 5 & 1 & -1 \end{bmatrix}^{\mathrm{T}},$$
$$z_1(0) = \begin{bmatrix} -1 & 1 & 2 \end{bmatrix}^{\mathrm{T}}, \quad z_2(0) = \begin{bmatrix} 1 & 4 & 1 \end{bmatrix}^{\mathrm{T}},$$
$$z_3(0) = \begin{bmatrix} 4 & 6 & 2 \end{bmatrix}^{\mathrm{T}}, \quad z_4(0) = \begin{bmatrix} -10 & 5 & -1 \end{bmatrix}^{\mathrm{T}},$$

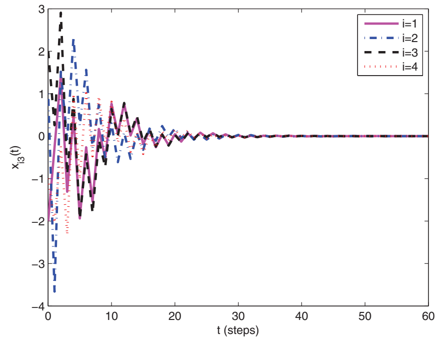

Fig. 4. Trajectories of the third state variables.

Initial conditions of estimate error (6) are chosen as

$$\begin{aligned}
e_1(0) &= \begin{bmatrix} 0.1 & -0.1 & -0.1 \end{bmatrix}^{\mathrm{T}},\\
e_2(0) &= \begin{bmatrix} 0.1 & 0.3 & 0.5 \end{bmatrix}^{\mathrm{T}},\\
e_3(0) &= \begin{bmatrix} 1 & 0 & -0.5 \end{bmatrix}^{\mathrm{T}},\\
e_4(0) &= \begin{bmatrix} 0.6 & 0 & -0.8 \end{bmatrix}^{\mathrm{T}},\\
e_1(-1) &= -\begin{bmatrix} 0.1 & 0.1 & 0.1 \end{bmatrix}^{\mathrm{T}},\\
e_2(-1) &= -\begin{bmatrix} 0.5 & 0.1 & 0.1 \end{bmatrix}^{\mathrm{T}},\\
e_3(-1) &= -\begin{bmatrix} 1 & 0.1 & 0.1 \end{bmatrix}^{\mathrm{T}},\\
e_4(-1) &= -\begin{bmatrix} 0.6 & 1 & 0.1 \end{bmatrix}^{\mathrm{T}},\\
e_1(-2) &= \begin{bmatrix} 0.1 & 0.3 & -0.1 \end{bmatrix}^{\mathrm{T}},\\
e_2(-2) &= \begin{bmatrix} -0.1 & 0.2 & 0.4 \end{bmatrix}^{\mathrm{T}},\\
e_3(-2) &= \begin{bmatrix} -0.6 & 0.5 & 0.1 \end{bmatrix}^{\mathrm{T}},\\
e_4(-2) &= \begin{bmatrix} 0.2 & 0.1 & -0.6 \end{bmatrix}^{\mathrm{T}}.
\end{aligned}$$

The state trajectories of NMAS (1) are shown in Figures 2–4, respectively, which demonstrates that states of NMAS (1) achieve consensus under protocol (3).

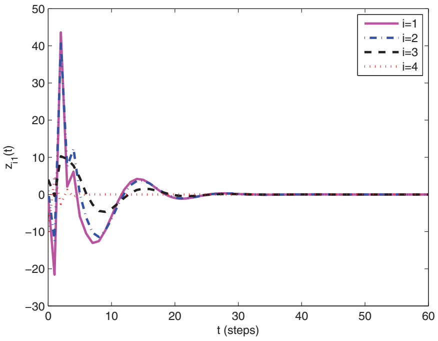

Fig. 5. Trajectories of the first protocol state variables.

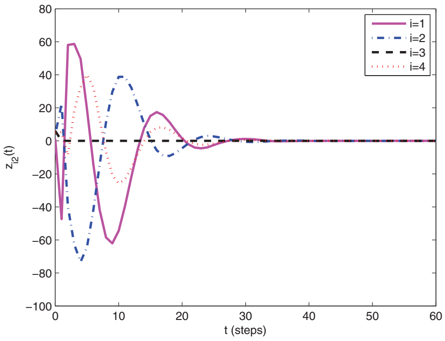

Fig. 6. Trajectories of the second protocol state variables.

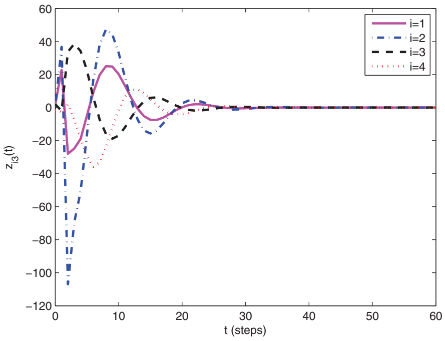

Fig. 7. Trajectories of the third protocol state variables.

The state trajectories of protocol (3) are shown in Figures 5–7, respectively. It is thus clear that protocol states asymptotically converge to zero.

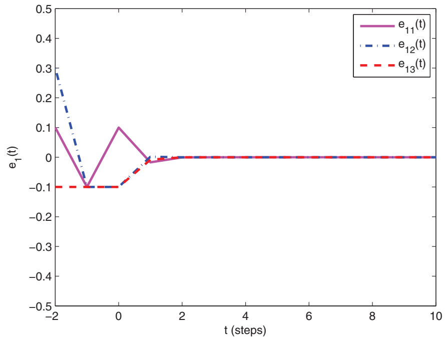

Fig. 8. The error trajectory $e_1(t)$.

The estimate error trajectories of observers are shown in Figures 8–11, respectively. It is obvious that states of observers track ones of NMAS (1).

## V. Conclusion

The consensusability problem of discrete-time linear NMASs with uniform dynamical agents and a communication delay has been investigated. A new distributed protocol is proposed by using the networked predictive control scheme. For discrete-time linear NMASs with a directed topology and

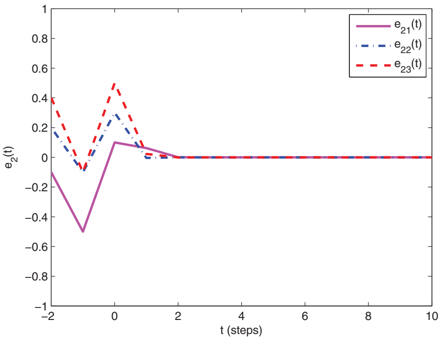

Fig. 9. The error trajectory $e_2(t)$.

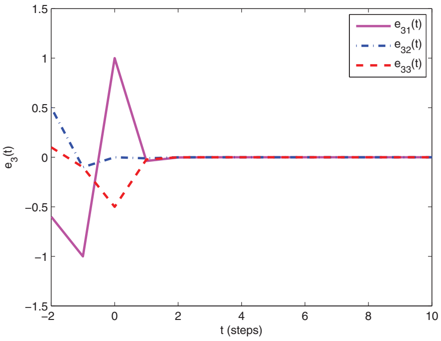

Fig. 10. The error trajectory $e_3(t)$.

a network delay, delay-independent necessary and/or sufficient criteria of consensusability have been obtained. A numerical example is provided to demonstrate the effectiveness of theoretical results.

*Abstract* — **The authors investigate the dynamical behaviour of a Duolever type of suspension on a standard sports motorcycle. The paper contains the modelling aspects of it, as well as the optimization process followed in order to obtain the suspension parameters and geometry arrangements. Head angle, wheelbase and normal trail are studied as indicators of the handling properties of the suspension system. Matlab optimization toolbox was used to design a mathematical model of a duolever front suspension system which keeps its normal trail constant during the full suspension travel. By using VehicleSim software, non-linear simulations were performed on motorcycle model that includes a duolever suspension. By a quasi-static variation of the forward speed of the motorcycle, the time histories of the system's states were obtained. The corresponded root locus to the linearized model were plotted and compared to those of the original motorcycle model without duolever system. A modal analysis was performed in order to get a deeper understanding of the different modes of oscillation and how the duolever system affects them. The results show that whilst a satisfactory anti-dive effect is achieved with this suspension system, it has a destabilizing effect on pitch and wobble modes.**

## I. Introduction

One of the most important factors on motorcycle stability is the front end. It links the front wheel with the main frame and has two main functions: the suspension of the front wheel and the steering of the motorcycle. Up to this date several suspension systems have been developed to reach the best behaviour of the front end, being the telescopic fork the most extended one. The Hossack/Fior (marketed as Duolever), decouples the suspension and steering functions. One of its advantages is that it can be designed to achieve a desirable performance when suspension action takes place in terms of wheelbase, trail and head angle. The purpose of this paper is to study the effect of a Duolever suspension system on the dynamical properties of high performance motorcycles. Making use of Duolever's configurable properties in terms of wheelbase, head angle and trail, an eventual alternative front suspension is designed. This is done making use of the mathematical modelling and simulation of a motorbike. It will predict the behaviour of the various systems and help to decide which one is the most appropriate as base of the alternative front suspension system. The authors base this work on an existing high fidelity model of a Suzuki GSX-R1000, extensively used and validated in previous research (see [1], [2] and [3]),. The suspension system is designed by using algebraic methods to ensure as a first approach that similar properties and parameters to the original design are kept so that they can be compared under equal conditions. This is; similar head angle, trail, masses and inertia, etc. Later on, parameters such as mass or inertia will be varied -always within the limits of engineering constrictions- to study their influence on the motorcycle's dynamical properties.

The structure of this paper is as follows: Section II introduces the high-fidelity motorbike mathematical model which forms the basis of this work including a description of the modelling software VehicleSim. Section III contains an explanation on the Duolever system. Parametrization methodology, optimization of the parameters and suspension behaviour are also included. Section IV discusses on the oscillation modes and stability issues arising from the Duolever suspension. Finally, the results are discussed in section V and some future research ideas are presented.

## II. Model Description

The model used is based on an existing model of a Suzuki GSX-R1000 used in the past for several contributions in the field of motorcycle dynamics and stability analysis (see [4], [5], [6], [7], [8]). It consist of seven bodies: rear wheel, swinging arm, main frame (comprising rider's lower body, engine and chassis), rider's upper-body, steering frame, telescopic fork suspension and front wheel assembly. It involves three translational and three rotational freedoms of the main frame, a steering freedom associated with the rotation of the front frame relative to the main frame and spinning freedoms of the road wheels. The road tires are treated as wide, flexible in compression and the migration of both contact points as the machine rolls, pitches and steers is tracked dynamically. The tyre's forces and moments are generated from the tyre's

978-1-4673-1560-9/12/$31.00 ©2012 IEEE

camber angle relative to the road, the normal load and the combined slip using Magic Formulae models [9] and [10]. This model is applicable to motorcycle tires operating at roll angles of up to 60$^{o}$.The aerodynamic drag/lift forces and pitching moment are modelled as forces applied to the aerodynamic centre and they are proportional to the square of the motorcycle's forward speed. In order to maintain steady-state operating conditions, the model contains a number of control systems, which mimic the rider's control action. These systems control the throttle, the braking and braking distribution between the front and rear wheels, and the vehicle's steering. For a detailed description of the complete model the reader is referred to [3]. It has been developed using VehicleSim [11], it is a set of LISP macros, enabling the description of mechanical multi-body systems. The outputs from VehicleSim are a simulation program based on "C"  language with the implementation of the equations of motion and a Matlab [12] file containing the model's linear state-space equations. VehicleSim commands are used to describe the components of the motorcycle multi-body system in a parent-child relationship according to their physical constraints and joints. Once the VehicleSim code generates the simulation program, this is capable of computing general motions corresponding to specified initial conditions and external forcing inputs.

## III. Duolever Suspension System

Following the scheme of double wishbone car's suspension systems, the Duolever suspension for motorcycles consists of two wishbones, one upright and a steering linkage. The wishbones can rotate around transverse axes and the upright is now a fork in which the front wheel is attached. In the car version the wheel spins in a perpendicular axis due to the position of the system which is placed in the side of the car. In the bike case, the system is placed in the front, so the wheel has to be rotated 90 degrees with respect to the car wheel. The connection of the fork with the two wishbones is made by ball joints which allow the wishbones rotate and the fork turns in the steering axis. The steering axis is defined by the ball joints centres. The steering linkage connects the handlebar with the fork. It is a system of two levers, connected by an axis, which can be compressed or elongated in order to reach the length between the handlebar and the fork.  See [13] and [14] for more detailed information about Duolever systems. Fig. 1 shows a schematic CAD design for a standard motorcycle fitted with a Duolever system: the different structural points of the duolever and the parameters defining its geometry have been marked in red. The spring-damper unit has not been included to help a clearer view.

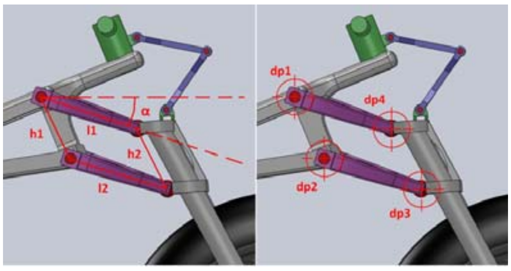

Figure 1. 3D kinematic components of a Duolever system. Parameters and points defining the Duolever geometry.

### A. Parametrization

The position of all the points is calculated in order to keep the model as close as possible to the configuration of the original motorbike described before. First of all, the parameters which must be considered in the design of the system the Duolever must be defined. These parameters are *l1*, *l2*, *h1*, *h2* and *α*. Where *l1* and *l2* are the lengths of the upper and lower wishbones, *h1* is the distance between the attachment points of the upper and lower wishbone, *h2* is the distance between the tips of the upper and lower wishbones and *α* is the nominal angle formed between the upper wishbone and the horizontal. With these parameters and the head angle the Duolever system is defined. The question is to find the attachment point to the main frame. To simplify this task the model of the motorbike is reduced to four main bodies: rear frame, front frame and two wheels. Two axes are considered: the rear-axis is the axis from the rear wheel attachment point to the point of attachment of the conventional front fork and, the front-axis, starting at this same point and forming the head angle with the vertical. The main points defined are:

*dp1: attachment point of upper wishbone in main frame.*

*dp2: attachment point of lower wishbone in main frame.*

*dp3: tip of the lower wishbone.*

*dp4: tip of the upper wishbone.*

*dp5: spring-damper unit in lower wishbone.*

*dp6: spring-damper unit in main.*

*pts: point located at the origin of the twist body in GSX-R1000 model when telescopic fork suspension was used. Now it is an auxiliary point located at the same position.*

In order to not modify the steering axis of the original model, *dp3* and *dp4* should be located on the front-axis and *dp1* is placed in the rear-axis to keep the delta-box configuration. Fig. 2 shows these points in the geometrical model.

### B. Optimization

#### 1) Suspension behaviour:

There exist four main parameters that mainly affect motorcycles´ handling. These are the wheelbase, the head angle, the trail and the normal trail. Wheelbase is the distance between the front wheel contact point and the rear wheel contact point. The head angle is the angle existing between the steering axis and the vertical axis. The trail is the distance between the front wheel contact point and the intersection of the steering axis with the road's plane. Finally, the normal trail is the distance between the front wheel contact point to the steering axis; it depends directly on the head angle and is just a perpendicular projection of the trail:

$$ntrail = trail \cdot cos(H_{ang})$$

For a Duolever suspension system the behaviour of the trails, wheelbase and head angle under suspension actuation depends on its design.

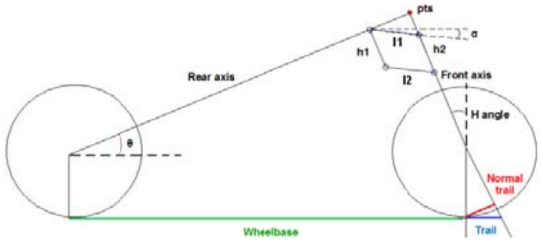

Figure 2. Points and angles defining the models geometry. Trail, head angle and wheelbase shown.

Whilst for a telescopic fork suspension system it is not possible to modify this behaviour, in a Duolever system the parameters *l1*, *l2*, *h1*, *h2* and *α* can be optimized in order to modify it. Fig. 3 shows this concept. For the (simplest) case of a parallelogram structure, the same result as for the conventional fork can be obtained due to the steering axis remains parallel to its initial direction along the full suspension travel.

*2) Parameters variations:*

The starting point for the optimization of the Duolever is to study the variation of the wheelbase and the normal trail with the suspension action. A geometrical model has been implemented on Matlab so that it allows tracking the eventual position of all the points in the assembly motorbike-Duolever along with the suspension travel, once the nominal position is known. The nominal position of the points *dp1*, *dp2, dp3* and *dp4* are given by the values of geometrical parameters. Considering the geometrical limitation of the motorcycle under study we took as a good approach the following values: *l1=170mm*, *l2=170mm*, *h1=120mm*, *h2=120mm* and *α=0.1rads*. A variation between the maximum and minimum *α* values (which have been calculated in order to produce an equivalent displacement of the motorbike as the conventional fork does) is performed, obtaining the geometrical position of all the points along the suspension travel. In Fig. 5 it is shown (dashed blue line) the behaviour of the wheelbase and the normal trail with the vertical suspension travel using the nominal set of parameters. Finally, in order to see how this behaviour changes according to Duolever parameters' variation, an external function has been developed. It takes an initial parameters vector and varies in a loop the parameter selected by the user. This loop calculates and stores the values of wheelbase and normal trail along the suspension travel for every value of the parameter varied. As an example, the 3D meshes representing the results obtained from the variation of geometrical parameter *α*, *l1* and *l2* are shown in Fig. 4. An *xz* reference axis that shows the nominal configuration is included in the figures.

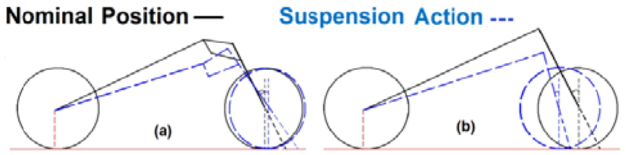

Figure 3. a) Duolever suspension system, head angle trail and wheelbase increase with the travel of the suspension. b) Telescopic fork suspension. Head angle, trail and wheelbase decrease with the travel of the suspension.

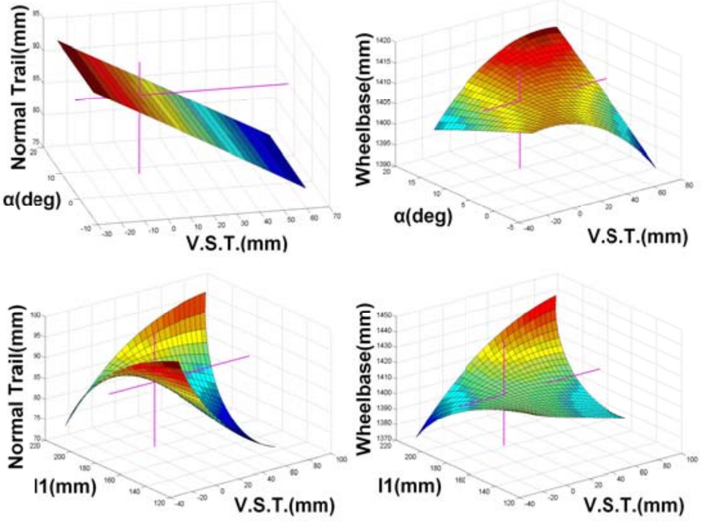

Figure 4. Behaviour variation with vertical suspension travel when parameters *α* and *l1* are modified.

As it can be seen, the variation with the parameters change is complicated enough to dissuade us to attempt a manual setting of them if we want to get constant trail or wheelbase. An automated optimization process is clearly needed to resolve this task.

*3) Optimization process:*

The goal is to find an optimal Duolever's parameter set such that the front suspension keeps the normal trail (so the trail and head angle) as constant as possible. A target function is defined and minimized by using Matlab optimization toolbox. This target function is the maximum difference -for a full suspension travel- between the nominal normal trail and the new normal trail depending on the set of parameters.

$$target = max(abs(ntrail-ntrail0))$$

Fig. 5 shows the behaviour of the wheelbase and normal trail for the optimized set of parameters in a solid green line. The values of these parameters are *l1=171mm*, *l2=182mm*, *h1=105mm*, *h2=124mm* and *α=0rad*. The nominal values of normal trail and wheelbase are plotted in dotted red lines. It can be seen how the lines for the optimized and standard Duolever cross each other at the initial value of the normal trail and the wheelbase but then their behaviour change completely. It is clear that the optimized set of parameter reduces almost to zero the variation in normal trail of the Duolever system.

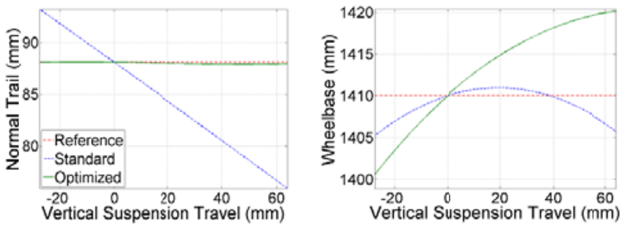

Figure 5. Wheelbase and normal trail behaviour with the vertical suspension travel for the geometrical standard and optimized models.

However, because we have used as target function the variation of the normal trail, the wheelbase is not kept constant but increases with the vertical suspension travel. Nevertheless this variation represents less than 1% and is not considered to be representative enough.

## IV. Oscillatory Modes and Stability Issues

One possible consequence of introducing new features and geometry changes in a motorcycle is that the stability of the system can be severely compromised. Motorbikes are nonlinear, oscillating complex systems that can represent a risk if they are not well damped. The modes under study are wobble and weave (see [4] for more details on these two modes). In this section the stability of the motorcycle model fitted with a Duolever type of suspension is analyzed by means of root locus diagrams in a similar manner as previous works such as [5], [6], [7] and [8]. Once the model with the optimized Duolever is built in VehicleSim, nonlinear simulations under different running conditions are performed and the linearized state space matrices of the system are fed with the nonlinear simulations states values in order to study the evolution of the eigenvalues over the operating envelope. Fig. 6 represents the root locus for the GSX-R1000 model with a telescopic fork (red +), a standard (blue x) and an optimized (green o) Duolever suspension systems. The roll angle for these simulations is 0 degrees and the swept variable is the forward speed ranging from 10 up to 80m/s. The stability properties of three characteristic modes will be analyzed: weave, wobble and pitch.

There are two main differences between the Duolever and the telescopic fork root locus plot. The wobble mode becomes unstable at medium speeds when a Duolever suspension is fitted in the model. Also, it can be seen that a "new" eigenvalue appears. This corresponds to the pitch mode. In the case of the telescopic fork it did not appear as it was well damped and greatly displaced on the left hand side of the complex plane. It lightly differs from the optimized and the standard Duolever models.

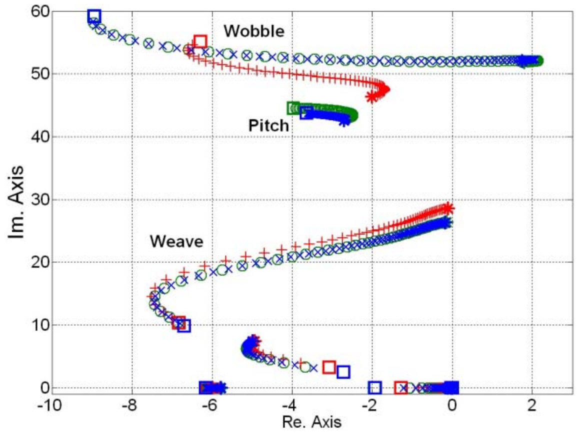

Figure 6. Root locus of the motorbike fitted with a telescopic fork (red+), a standard (blue x) and an optimized Duolever (green o) for 0 degrees of roll angle and a speed going from 10 (squares) up to 80 m/s (stars).

In order to find what eigenvalue it was and where it came from, the eigenvectors of the model with the Duolever system were compared with the eigenvectors of the model with telescopic fork system. As the eigenvalues for the optimized and standard Duolever models are very similar the comparison between eigenvectors has been done only for the optimized Duolever model. The comparison in Fig. 7 shows the modulus of the components of the eigenvectors. Only the generalized speeds are shown on the bar diagram. On the left side for each component, the value for the optimized Duolever is shown in green and on the right; the correspondent value to the telescopic fork is shown in red. The components of each eigenvector are labelled as follows:

| | |
|---|---|
| *XT, YT, ZT:* | *Translation of main body.* |
| *XR, YR, ZR:* | *Rotation of main body (Roll, Pitch, Yaw).* |
| *RSP and FSP:* | *Compression of rear and front springs.* |
| *RW and FW:* | *Rotation of rear and front wheel.* |
| *UBR:* | *Rotation of riders´ upper body.* |
| *STR:* | *Rotation of steer axis.* |
| *TWS:* | *Rotation of twist axis.* |

It has to be noted that the Duolever mathematical model was defined without flexibility, that means that it will have not twist degree of freedom, hence this coordinate will only appear for the telescopic fork model. It can be seen that there exist a high symmetry between the modes of the telescopic fork and the optimized Duolever models. There is a similar pattern in their components except for the twist generalized coordinate. For the Duolever case the twist degree of freedom has not been included, leaving this for the next step of this research.

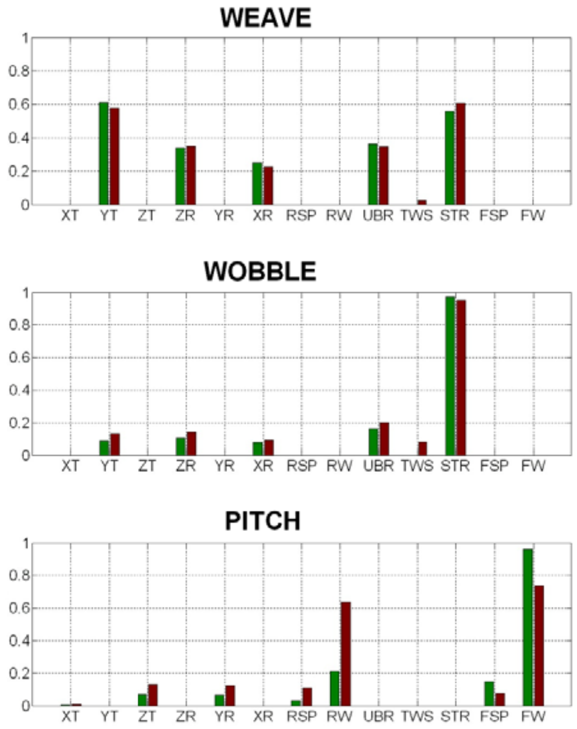

Figure 7. Eigenvector components for weave, wobble and pitch modes. Duolever suspension in green on the left, telescopic fork in red on the right.

Weave and wobble are out-of-plane modes. For both Duolever and telescopic fork cases, it is shown that the contribution of the various degrees of freedom to their eigenvectors is similar. On the other hand, pitch is an in-plane mode, the oscillation takes place in the symmetry plane of the motorbike, but for the Duolever case, the front wheel contribution becomes more relevant than in the fork suspension case whilst the contribution of the rear wheel is less. Also the front suspension coordinate increases its relevance and rear suspension decreases it. Finally the amplitude for the rotation in *y* and translation *z* (which implies the pitching of the main body) is reduced. Considering this, we can think of an oscillation about the front wheel which cannot be damped effectively by the front suspension. In order to check this, several simulations have been performed introducing various values of front tire damping coefficient. Fig. 8 shows these results for various values of damping. The weave and wobble modes appear as in Fig. 6 for both the telescopic and Duolever cases. The pitch mode appearing for the Duolever case changes according to various values of front tyre damping coefficient.

In the light of results shown in Fig. 8, it can be seen how the Duolever suspension does not damp pitch oscillations as effectively as the fork suspension does. This is a consequence of the Duolever's geometry and the anti-dive effect that it provides, reason why a Duolever suspension does not dive whilst performing braking action. The front assembly has a main role in the motorbike dynamic and in the case of the Duolever model its design becomes relevant for the pitch mode. In order to illustrate this, a straight running, front wheel braking simulation was carried out. The vertical suspension travel is shown in Fig. 9.a and the pitch rotation of the main body is shown in Fig. 9.b. The force applied in the front brake was calculate to provide the same deceleration of 1.5m/s$^2$ for all the three cases: telescopic fork (red), standard (blue) and optimized Duolever (green).

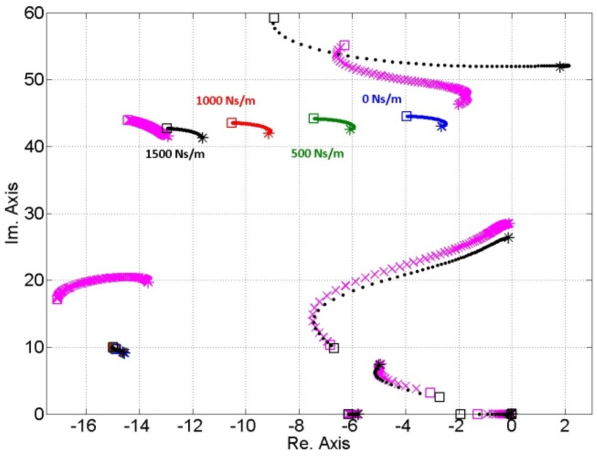

Figure 8. Root locus for the model of the motorcycle fitted with a telescopic fork (magenta +) and an optimized Duolever (blue ▪, green ▪, red ▪ and black ▪) for 0 degrees of roll angle and speed being swept from 10 (squares) up to 80m/s (stars). The damping of the front wheel is varied from 0 Ns/m up to 1500 Ns/m.

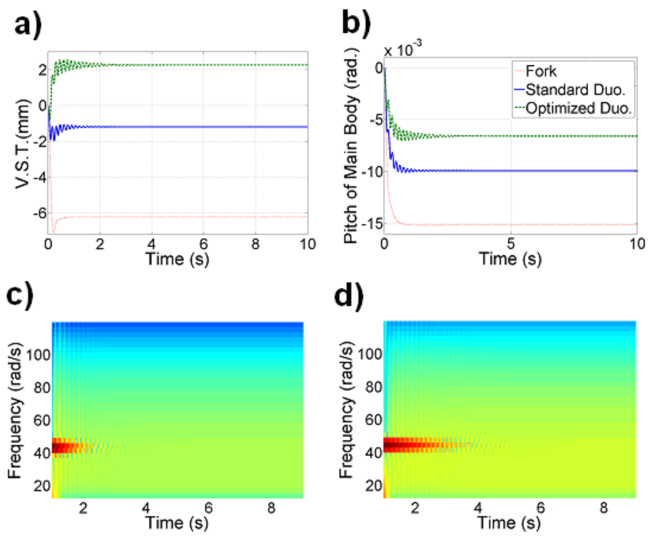

Figure 9. a) Vertical Suspension Travel for a braking simulation of 1.5m/s$^2$, b) Pitch of the Main Body for a braking simulation of 1.5m/s$^2$, c) Spectrogram of the Vertical Suspension Travel for the standard Duolever model during the braking simulation, d) Spectrogram of the Vertical Suspension Travel for the optimized Duolever model during the braking simulation.

It can be seen how whilst the front fork dives about 6mm, the standard Duolever does it only less than 1.2mm and the optimized Duolever does not dive but rises about 2.2mm. This behaviour appears due to the Duolever geometry which was optimized to get a constant trail. Other effect seen in this figure is the oscillation for Duolever systems, being higher and larger in time for the optimized one. In order to get a better understanding a spectrogram of the signal was done. It was used a 2 seconds time window with an overlapping of 99% to get good compromise between time and frequency resolutions. The low and high frequency components were neglected in this plot. The results are shown in Fig. 9.c for the standard and Fig. 9.d for the optimized Duolever. Due to the size of the window (2 secs.) the spectrograms for the first and the last seconds cannot be displayed. However, in both plots, oscillations about 43rad/s can be clearly recognized, they propagate reducing their amplitudes until they disappear. It can be seen how for the optimized Duolever the oscillation is sustained up to 4 seconds, whilst for standard Duolever model it disappears about 2.5 seconds.

The root locus plots showed that the frequency of the pitch mode is around 43rad/s at 80m/s, which is the initial speed of the motorcycle in the braking simulation case. This mode that becomes less stable with the Duolever front suspension system is prone to affect the behaviour of the motorcycle, representing a handicap for these type of suspension systems.

From these simulations it is clear to see that fitting a Duolever suspension system produces instability in the wobble mode. Wobble mode depends mainly on three factors that need to be taken into account: the mass and inertia of the front assembly and the damping ratio of the steering damper. If a high value of damping ratio is used, a more stable steering will be found at high speeds but it will be much less manoeuvrable at low speeds. Also, as it has shown in [6], increasing the steering damping coefficient the weave mode becomes less stable. Several commercial motorcycles with telescopic fork suspensions include steering dampers whose damping coefficients are variable with the speed. At the moment, the authors are investigating the possible benefits of including a speed dependant steering damper in the case of a Duolever suspension type. These results will be presented in a separate report.

## V. Conclusions

The mathematical model used for this study corresponds to a Suzuki GSX-R1000. This motorbike is not fitted with a Duolever, it is designed to make use of a telescopic fork. The mathematical model was modified with a carefully designed new suspension system model based on reasonable assumptions. Some dynamical properties about this type of suspension system have been studied.

The Duolever suspension can be designed in order to get a determined behaviour of the wheelbase, the head angle or the trail and the normal trail. In this study, a configuration which provides a constant normal trail along all the suspension travel for a Duolever system was obtained.

In general, a Duolever suspension system provides an anti-dive effect due to tyre's contact patch curvilinear trajectory. One of the consequences of the optimization of the Duolever is the increased anti-dive effect that appears compared to the standard Duolever suspension with a parallelogram design.

The anti-dive effect would represent in most cases beneficial characteristics but, in terms of oscillating behaviour, the pitch mode becomes clearly less damped compared to the case of standard telescopic fork suspension, representing in this way a possible risk issue under certain running conditions.

The advantages of the Duolever suspension system are meant to be the comfort, the manoeuvrability and the better performance of the front suspension, keeping the trails almost constant for all the suspension travel and presenting a relevant anti-dive effect. This allows the suspension to be fully operative on braking. However, it has been shown that less stable pitch modes are associated to this system.

It has also been shown how after including this suspension system in the model of a motorcycle which has not been designed to fit this type of suspensions, the wobble mode becomes unstable at high roll angles and medium-moderate speeds. In order to get wobble stability for the Duolever case, possibly a more complex steering damper unit depending on the speed should be design, or an inerter could be included. These possible solutions are currently under investigation by the authors.
